## FEATURES

RF output frequency range: $\mathbf{2 7} \mathbf{~ G H z}$ to $31 \mathbf{G H z}$ Two upconversion modes

Direct upconversion from differential baseband I/Q (I/Q mode)
Single upper sideband upconversion (IF mode)
1 dB bandwidth: 500 MHz (I/Q mode)
Input frequency range: $\mathbf{2 ~ G H z}$ to $\mathbf{3} \mathbf{~ G H z}$ (IF mode)
Matched, $50 \Omega$, single-ended RF output
Matched, $50 \Omega$, single-ended IF input
Programmable baseband I/Q common mode-voltage
Sideband rejection and carrier feedthrough optimization
Combined RF and IF gain dynamic range: $\mathbf{7 0}$ dB
Programmable automatic IF gain control
Programmable via 3-wire or 4-wire SPI
40-terminal, $6 \mathbf{m m} \times 6 \mathbf{m m}$, RoHS compliant LGA

## APPLICATIONS

## Satellite communication

Point to point microwave communication

## GENERAL DESCRIPTION

The ADMV4530 is a highly integrated upconverter with an in-phase/quadrature (I/Q) mixer that is ideally suited for next generation Ka band satellite communications.
An integrated low phase noise, fractional-N phase-locked loop (PLL) with a voltage controlled oscillator (VCO) and internal $2 \times$ multiplier generate the necessary on-chip local oscillator (LO) signal for the I/Q mixer, eliminating the need for external frequency synthesis. The VCO uses an internal autocalibration routine that allows the PLL to select the necessary settings and locks in approximately $100 \mu \mathrm{~s}$.
The single-ended reference input to the PLL operates up to 500 MHz and features internal reference dividers and a multiplier for added flexibility. Additionally, the phase frequency detector (PFD) comparison frequency can be up to 250 MHz for integer mode and 160 MHz for fraction- N mode.
The upconverter consists of an I/Q mixer that can operate in either I/Q mode with 500 MHz of bandwidth or in IF mode up to 3 GHz of bandwidth, which allows various radio architectures and backward compatibility with legacy systems.

Immediately following the I/Q mixer are stages of gain and variable attenuation. The configuration can achieve a minimum 1 dB compression point ( $\mathrm{P} 1 \mathrm{~dB} \mathrm{)} \mathrm{compression}$ point of 19 dBm , eliminating the need for external stages of gain.
A programmable 4-wire serial port interface (SPI) allows adjustment of the quadrature phase for optimum sideband suppression. In addition, the SPI allows nulling of LO feedthrough in IF mode. In I/Q mode, the LO feedthrough can be nulled by applying external dc offset to the differential baseband I/Q inputs.

An IF automatic gain control (AGC) adjusts the IF variable gain amplifier (VGA) to compensate for input power variations. During normal operation, this AGC feature can be enabled or disabled via the SPI. When disabled during normal operation, the AGC feature only works on a test tone during power-down mode to track temperature variations.
The ADMV4530 upconverter comes in a RoHs compliant, $6 \mathrm{~mm} \times 6 \mathrm{~mm}$, 40-terminal land grid array (LGA) package. The ADMV4530 operates over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ case temperature range.

## ABSOLUTE MAXIMUM RATINGS

Table 4.

| Parameter | Rating |
| :--- | :--- |
| VCC_DRV, VCC_AMP, and VCC2_DRV | 5 V |
| VCC_IF, VCC2_IF, VCC_VVA, | 4.3 V |
| VCC_MIXER, VCC_DOUBLER, |  |
| VCC_BG | 3.6 V |
| VCC_VCO, VCC_DIV, VCC_LDO, |  |
| VCC_CP | 2.3 V |
| VCC_1P8V | -0.3 V to +2.1 V |
| REF_IN to GND |  |
| Inut Power | 10 dBm |
| IF | 5 dBm |
| I/Q |  |
| Temperature | $125^{\circ} \mathrm{C}$ |
| Junction | $10^{6}$ hours |
| Lifetime at Maximum Junction | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| (T,) | $-55^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Operating Range | $260^{\circ} \mathrm{C}$ |
| Storage Range | $\mathrm{MSL3}$ |
| Lead Range (Soldering 60 sec) |  |
| Moisture Sensitivity Level (MSL) |  |
| Rating |  |
| Electrostatic Discharge (ESD) | 1000 V |
| Sensitivity |  |
| Human Body Model (HBM) |  |
| Field Induced Charged Device | 1000 V |
| $\quad$ Model (FICDM) |  |

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL INFORMATION

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.
$\theta_{\mathrm{JA}}$ is the natural convection junction to ambient thermal resistance measured in a one cubic foot sealed enclosure. $\theta_{\text {Jc }}$ is the junction to case thermal resistance.
Only use $\theta_{\mathrm{JA}}$ and $\theta_{\mathrm{JC}}$ to compare the thermal performance of different packages when all test conditions listed are similar to JEDEC specifications. Otherwise, use $\Psi_{J T}$ and $\Psi_{J \text { I }}$ to calculate the device junction temperature using the following equations:

$$
\begin{equation*}
T_{J}=\left(P \times \Psi_{J T}\right)+T_{T O P} \tag{1}
\end{equation*}
$$

where:
$P$ is the total power dissipation in the chip (W).
$\Psi_{J T}$ is the junction to top thermal characterization number.
$T_{T O P}$ is package top temperature $\left({ }^{\circ} \mathrm{C}\right) . T_{T O P}$ is measured at the top center of the package.

$$
\begin{equation*}
T_{J}=\left(P \times \Psi_{J B}\right)+T_{B O A R D} \tag{2}
\end{equation*}
$$

where:
$P$ is the total power dissipation in the chip (W).
$\Psi_{J B}$ is the junction to board thermal characterization number.
$T_{\text {BOARD }}$ is the board temperature measured on the midpoint of the longest side of the package, no more than 1 mm from the edge of the package body $\left({ }^{\circ} \mathrm{C}\right)$.
As stated in JEDEC51-12, only use Equation 1 and Equation 2 when no heat sink or heat spreader is present. When a heat sink or heat spreader is added, use $\theta_{\text {J__тор }}$ or $\theta_{\text {Jс_вот }}$ (Table 6) to estimate or calculate the junction temperature. The preferred heat sink or heat spreader placement for this device is to contact the bottom of the board that has enough number of thru vias thermally connecting the bottom paddle of the device to the heatsink along with an appropriate thermal insulating material (TIM) to efficiently reduce the junction temperature of the device.
Table 5 shows the temperature rise from case to junction ( $\Delta \mathrm{T}_{\mathrm{fc}}$ ) based on a detailed power map on a JEDEC (JESD512) board as opposed to a JEDEC thermal characterization number used to get the average temperature due to uniform power dissipation across the ADMV4530 die. This would result in a higher calculated junction temperature but sets the correct limit to the maximum case temperature with the ADMV4530 mounted on a JEDEC board. There is one $\Delta \mathrm{T}_{\mathrm{JC}}$ value that applies for both modes of operation.

To calculate $T_{B O A R D, \max }$ (Maximum case temperature referred to the bottom of the package/ nearest point on the board to the package) use Equation 3 and Equation 4 and refer to Figure 2:
$T_{B O A R D, M A X}=T_{J, M A X}-\Delta T_{J C}-P \times \theta_{J C_{-} B O T}$
if bottom side is applied to the PCB bottom surface then:

$$
\begin{equation*}
T_{B O A R D}=T_{\text {BASE_PLATE }}+P \times \theta_{\text {BOARD }}+P \times \theta_{\text {TIM }} \tag{4}
\end{equation*}
$$

where:
$P$ is the total power dissipation in the chip (W).
$T_{\text {J, MAX }}$ is the maximum junction temperature $\left({ }^{\circ} \mathrm{C}\right)$ in Table 4.
$T_{B O A R D, M A X}$ is the maximum board temperature measured on the midpoint of the longest side of the package no more than 1 mm from the edge of the package body $\left({ }^{\circ} \mathrm{C}\right)$ $\Delta T_{J C}$ is the highest temperature rise $\left({ }^{\circ} \mathrm{C}\right)$ from case to junction in Table 5.
$T_{B O A R D}$ is the board temperature measured on the midpoint of the longest side of the package no more than 1 mm from the edge of the package body $\left({ }^{\circ} \mathrm{C}\right)$
$T_{\text {BASE_PLATE }}$ is the temperature of the base plate of the heatsink
$\theta_{\text {TIM }}$ is the thermal resistance $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$ of the TIM $\theta_{\text {BOARD }}$ is the thermal resistance $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$ of the board $\theta_{J C_{-} B o t}$ is the junction to top case thermal resistance $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$ in Table 6.

Figure 2. Circuit Level Description of Power Map (left) and Uniform Power Dissipation Methods (right)

Table 5. Thermal Rise from Case to Junction

| Operational Mode | $\Delta \mathrm{T}_{\mathrm{JC}}$ | Unit |
| :--- | :--- | :--- |
| IF and I/Q mode | 32 | ${ }^{\circ} \mathrm{C}$ |

The thermal resistance of the ADMV4530 assuming the JEDEC standard of uniform power dissipation based on a JEDEC (JESD51-2) board is shown in Table 6. Thermal resistance based on a uniform power dissipation is useful to compare the performance of the ADMV4530 to other similar ICs.

Table 6. Thermal Resistance

| Package <br> Type | $\boldsymbol{\theta}_{\text {J__вот }^{\mathbf{1}}}{ }^{1}$ | $\boldsymbol{\theta}_{\text {JC_top }}{ }^{\mathbf{1}}$ | $\boldsymbol{\Psi}_{\text {JT }}$ | $\boldsymbol{\Psi}_{\text {JB }}$ | $\boldsymbol{\theta}_{\text {JA }}$ | Unit |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $C C-40-8$ | 3.9 | 11.7 | 3.0 | 8.5 | 28.2 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

${ }^{1}$ See JEDEC Standard JESD51-2 for additional information on optimizing the thermal impedance.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES

1. NC = NO CONNECTION.
2. EXPOSED PAD. CONNECT THE EXPOSED PAD
TO RF AND DC GROUND.
商

Figure 3. Pin Configuration

Table 7. Pin Function Descriptions

| Pin <br> No. | Mnemonic | Description |
| :---: | :---: | :---: |
| $\begin{aligned} & 1,12, \\ & 40 \end{aligned}$ | VCC_DRV, VCC_AMP, VCC2_DRV | Supply Voltages for the RF Output Driver, 4.0 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to each pin. |
| 2, 3, 14 | NC | No Connection. |
| 4 | VCTR_RF | RF Gain Control, 0 V to 1.8 V . Apply voltage to VCTR_RF after all other supply pins have been powered. If that is not possible, then be sure to install approximately $1 \mathrm{k} \Omega$ in series with VCTR_RF. |
| $\begin{aligned} & 5,6,8 \\ & 9 \end{aligned}$ | QN, QP, IP, IN | Differential Quadrature Baseband Inputs. These $100 \Omega$ differential impedance inputs can be common-mode dc biased from 0 V to 2.5 V . |
| 7,16 | VCC_IF, VCC2_IF | Supply Voltages for the IF and Baseband Inputs, 3.3 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to each pin. |
| 10 | EXT_CAP_N (VCTR_IF) | IF Gain Control Capacitor Negative Terminal. To adjust the IF gain manually, this pin must be driven externally when the AGC functionality is disabled, 0 V to 3.3 V . Note that VCTR_IF is the voltage applied to the EXT_CAP_x pins. Apply voltage to EXT_CAP_N after all other supply pins have been powered. If that is not possible, then be sure to install approximately $1 \mathrm{k} \Omega$ in series with EXT_CAP_N. |
| 11 | EXT_CAP_P | IF Gain Control Capacitor Positive Terminal. Note that VCTR_IF is the voltage applied to the EXT_CAP_x pins. |
| 13 | VCC_VVA | Supply Voltage for the Variable Gain Amplifier, 1.8 V . Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 15 | VCC_MIXER | Supply Voltage for the Mixer, 3.3 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 17 | VCC_DOUBLER | Supply Voltage for the Internal $2 \times$ Multiplier, 3.3 V . Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 18 | IF | IF Input. This pin has a $50 \Omega$ input impedance. |
| 19 | RBIAS | Resistor Band Gap Reference Bias. Place a precision $680 \Omega$ resistor to ground at this pin. |

| Pin <br> No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 20 | VTUNE | VCO Tune Port, 0.5 V to 2.8 V . This pin is driven by the output of the loop filter. |
| 21 | VCC_BG | Supply Voltage for the Internal Band Gap, 3.3 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 22 | VG_VCO | VCO Gate Decoupling. Place a $10 \mu \mathrm{~F}$ decoupling capacitor at this pin. |
| 23 | VCC_VCO | Supply Voltage for the VCO, 3.3 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 24 | VCC_DIV | Supply Voltage for Fractional-N PLL, 3.3 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 25 | PD | Power-Down, 3.3 V Logic. Active high. |
| 26 | CPOUT | Charge Pump Output. Connect this pin to VTUNE (Pin 20) through the loop filter. |
| 27 | $\overline{C S}$ | SPI Chip Select. 3.3 V logic. Active low. |
| 28 | SDI | SPI Data Input. 3.3 V logic. |
| 29 | SCLK | SPI Clock. 3.3 V logic. |
| 30 | SDO | SPI Data Output. 3.3 V logic. |
| 31 | CREG | External Capacitor for the Low Dropout (LDO) Regulator Output. Place a $0.1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 32 | VCC_LDO | Supply Voltage for the Internal LDO Regulator, 3.3 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 33 | VCC_CP | Supply Voltage for the Charge Pump, 3.3 V. Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. |
| 34 | $\overline{\text { RST }}$ | Reset. 3.3 V logic. Active low. |
| 35 | REF_IN | PLL Reference Input. Apply an external reference signal to this pin with a $0.01 \mu \mathrm{~F}$, dc blocking capacitor. Refer to Figure 91 for the external reference input configuration. |
| 36 | VCC_1P8V | Supply Voltage for the SPI Block, 1.8 V . Place a $1 \mu \mathrm{~F}$ decoupling capacitor close to this pin. The voltage on VCC_1P8V should be applied at the same time or after all other supply pin voltages have been applied. |
| 37, 39 | GND | Ground. Connect these pins to RF and dc ground. |
| 38 | RFOUT | RF Output. This pin has a $50 \Omega$ output impedance. |
|  | EPAD | Exposed Pad. Connect the exposed pad to RF and dc ground. |

## TYPICAL PERFORMANCE CHARACTERISTICS

## I/Q MODE

$\mathrm{I} / \mathrm{Q}$ frequency $=25 \mathrm{MHz}, \mathrm{I} / \mathrm{Q}$ input power $=-10 \mathrm{dBm}, \mathrm{RF}$ frequency $=29 \mathrm{GHz}, 1 \mathrm{MHz}$ tone spacing, upper sideband, R_WORD $=2$, CP_CURRENT $=4.20 \mathrm{~mA}$, REF_IN power $=8 \mathrm{dBm}$, REF_IN frequency $=200 \mathrm{MHz}$, loop filter bandwidth $=540 \mathrm{kHz}$, VCC_DRV = VCC_AMP $=$ VCC2_DRV $=4 \mathrm{~V}, \mathrm{VCC}$ _IF $=$ VCC2_IF $=$ VCC_VVA $=$ VCC_MIXER $=$ VCC_DOUBLER $=$ VCC_VCO $=$ VCC_DIV $=$ VCC_LDO $=$ VCC_CP $=3.3$ $\mathrm{V}, \mathrm{VCC}$ _1P8V $=1.8 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=+25^{\circ} \mathrm{C},-40^{\circ} \mathrm{C}$, and $+85^{\circ} \mathrm{C}, \mathrm{V} \mathrm{CM}=0.5 \mathrm{~V}, \mathrm{VCTR}$ RF $=1.8 \mathrm{~V}$, and board losses de-embedded to the device, unless otherwise noted.

## UPCONVERTER M × N SPURIOUS PERFORMANCE

Mixer spurious products are measured in dBc from the RF output power level.
For IF mode, spurious frequencies are calculated by

$$
|(\mathrm{M} \times \mathrm{IF})+(\mathrm{N} \times \mathrm{LO})|
$$

For I/Q mode, spurious frequencies are calculated by
$|(\mathrm{M} \times \mathrm{I} / \mathrm{Q})+(\mathrm{N} \times \mathrm{LO})|$

## IF Mode

IF frequency $=2715 \mathrm{MHz}, \mathrm{RF}$ frequency $=29 \mathrm{GHz}, \mathrm{RF}$ output power $=10 \mathrm{dBm}$, VCTR_RF $=1.8 \mathrm{~V}$, and VCTR_IF $=0 \mathrm{~V} . \mathrm{N} / \mathrm{A}$ means not applicable.

## THEORY OF OPERATION

The ADMV4530 integrates a fractional-N PLL, VCO, internal $2 \times$ multiplier, and I/Q mixer. The fractional-N PLL locks the VCO to a precise reference input signal for low noise operation. The VCO signal is then multiplied by the internal $2 \times$ multiplier to generate the necessary LO signal for the I/Q mixer. The I/Q mixer can operate with either differential baseband I/Q inputs or a single-ended IF input. The functionality of the various blocks within the ADMV4530 follows within this section.

## SPI CONFIGURATION

The SPI of the ADMV4530 allows configuration of the device for specific functions or operations via the 4-pin SPI port. This interface provides users with added flexibility and customization. The SPI consists of four control lines: SCLK, SDI, SDO, and $\overline{C S}$. The ADMV4530 protocol consists of a write/read bit followed by 15 register address bits and 8 data bits. The address field and data field are organized MSB first and end with the LSB.

For a write operation, set the MSB to 0 , and for a read operation, set the MSB to 1 . The write cycle must be sampled on the rising edge of SCLK. The 24 bits of the serial write address and data are shifted in on the SDI control line, MSB to LSB. The ADMV4530 input logic level for the write cycle supports a 3.3 V interface.
For a read cycle, the R/W bit and the 15 bits of address shift in on the rising edge of SCLK on the SDI control line. Then, 8 bits of serial read data shift out on the SDO control line, MSB first, on the falling edge of SCLK. The output logic level for a read cycle is 3.3 V . The output drivers of the SDO are enabled after the last rising edge of SCLK of the instruction cycle and remain active until the end of the read cycle. In a read operation, when $\overline{\mathrm{CS}}$ is deasserted, SDO returns to high impedance until the next read transaction. The $\overline{\mathrm{CS}}$ is active low and must be deasserted at the end of the write or read sequence.
An active low input on $\overline{\mathrm{CS}}$ starts and gates a communication cycle. The $\overline{\mathrm{CS}}$ pin allows more than one device to be used on the same serial communications lines. The SDO pin goes to a high impedance state when the $\overline{\mathrm{CS}}$ input is high. During the communication cycle, the chip select must stay low. The SPI communications protocol follows the Analog Devices, Inc., SPI standard. For more information, see the ADI-SPI Serial Control Interface Standard (Rev 1.0).

## REGISTER MAP SECTIONS

The ADMV4530 consists of three register map sections. The first section spans from Register 0x000 through Register 0x00D and follows the standard Analog Devices SPI protocol, which includes protocol setup and device identification registers. The second register map section starts at Register 0x010 through Register 0x07C and contains all of the relevant PLL control registers. The third register map section starts at Register 0x100 through Register $0 \times 119$ and contains all of the mixer and baseband control registers. To read back the register values from the
first and third sections, the REG_PAGE_SEL bits in Register $0 \times 117$ must be set to 1 , and to read back from the PLL section, the REG_PAGE_SEL bits in Register 0x117 must be set to 0 .

## DOUBLE BUFFERED REGISTERS

The PLL inside the ADMV4530 contains several double buffered bit fields that take effect only after a write to the lower portion of the N counter integer value (Register $0 \times 010$ ). This register applies any changes to these double buffered bit fields and initiates the autocalibration routine. The following is a list of the double buffered bit fields and their corresponding registers:

- REF_X2_EN (Register 0x022)
- RDIV2 (Register 0x022)
- R_WORD (Register 0x01F)
- CP_CURRENT (Register 0x01E)
- FRAC2WORD (Register 0x017 and Register 0x018)
- FRAC1WORD (Register 0x014 through Register 0x017)
- MOD2WORD (Register 0x019 and Register 0x01A)
- BIT_INTEGER_WORD (Register 0x010 and Register 0x011)

## START-UP INITIALIZATION SEQUENCE

Upon powering up or resetting the ADMV4530, it is recommended to program the register map in reverse order, starting with the highest register number first. The reverse order ensures that the double buffered registers are programmed prior to initiating the autocalibration routine and that all PLL control settings are in their correct state. The recommended values of each register are shown in both the Register Summary section and the Register Details section. The following describes the recommended programming sequence:

1. Program Register $0 \times 000$ to a value of $0 \times 18$ to enable the SDO pin.
2. Program Register $0 \times 117$ to a value of $0 \times 4 \mathrm{C}$ to enable reading from the mixer section of the register map.
3. Program Register 0x100 through Register 0x119 in reverse order based upon the desired mixer settings.
4. Program Register $0 \times 117$ to a value of $0 \times 0 \mathrm{C}$ to enable reading from the PLL section of the register map.
5. Program Register 0x010 through Register 0x07C in reverse order based upon the desired PLL settings.

## FREQUENCY UPDATE SEQUENCE

After the initialization sequence is performed, the output frequency can be updated by programming Register 0x010 through Register 0x01A in reverse order.

## REFERENCE INPUT

Figure 91 shows the single-ended reference input stage. There is an internal reference multiply by 2 block ( $\times 2$ doubler) that allows generation of higher $\mathrm{f}_{\text {PFD }}$. A higher $\mathrm{f}_{\text {PFD }}$ is useful for improving overall system phase noise performance. Typically, doubling the fPFD improves the in band phase noise performance by up to $3 \mathrm{dBc} / \mathrm{Hz}$. Use the REF_X2_EN bit (Register 0x022, Bit 5) to enable the reference doubler, which toggles the SW1 switch, shown in Figure 91.
Following the reference doubler block, there are two frequency dividers: a 5-bit R counter ( 1 to 32 allowed) and a divide by 2 block. These dividers allow the input REF frequency to be divided down to produce lower $\mathrm{f}_{\text {PFD }}$ that helps minimize fractional- N integer boundary spurs at the output.
Use the R_WORD bits (Bits[4:0]) in Register 0x01F to set the R counter. If the R_WORD = 1, the SW2 switch is in the position shown in Figure 91. Otherwise, the SW2 switch toggles to use the R counter. Additionally, R_WORD $=0$ corresponds to a divide by 32 value for the $R$ counter. To enable the reference divide by 2 block, use the RDIV2 bit (Register 0x022, Bit 4) which toggles the SW3 switch, shown in Figure 91.

## N COUNTER

The N counter allows a division ratio in the PLL feedback path from the VCO. Note that the VCO signal is multiplied by 2 to achieve the LO frequency at the input of the mixer. The division ratio is determined by using the Integer N (INT), fractional-N (FRAC), and modulus (MOD) values that this counter comprises. The applicable registers for setting the INT, FRAC, and MOD values are Register 0x010 to Register $0 \times 01 \mathrm{~A}$.

## PRESCALER AND PRESCALER BIAS

There is two prescalers prior to the $N$ counter, the $4 / 5$ prescaler and the $8 / 9$ prescaler. During operation, only one prescaler can be selected, using the PRE_SEL bit (Register 0 x 012 , Bit 5 ). The $8 / 9$ prescaler is currently not supported. Only use the $4 / 5$ prescaler.
There is bias control for the prescaler, using the RF_PBS bits (Register 0x027, Bits[1:0]). For temperature less than or equal to $0^{\circ} \mathrm{C}$, set these bits to value 1 . For temperature greater than $0^{\circ} \mathrm{C}$, set these bits to value 2 .

## INT, FRAC, MOD, AND R COUNTER RELATIONSHIP

The INT, FRAC, and MOD values, in conjunction with the reference path, make it possible to generate VCO frequencies spaced by fractions of the $\mathrm{f}_{\text {PFD }}$. To calculate $\mathrm{f}_{\text {PFD }}$, use the REF_IN frequency and the reference path configuration parameters as follows:

$$
f_{P F D}=R E F_{-} \text {IN Frequency } \times \frac{1+D}{R \times(1+T)}
$$

where:
$D$ is the reference doubler bit ( 0 or 1 ).
$R$ is the reference divide ratio of the binary, 5 -bit
programmable counter (1 to 32).
$T$ is the reference divide by 2 bit ( 0 or 1 ).
To calculate the VCO frequency ( fvco ), use the following equation:

$$
f_{V C O}=f_{L O} / 2=f_{P F D} \times N
$$

where:
$f_{L O}$ is the frequency of the LO driving the mixer.
$N$ is the desired value of the N counter.
The N counter value is defined by the following:

$$
N=I N T+\frac{F R A C 1+\frac{F R A C 2}{M O D 2}}{M O D 1}
$$

where:
$I N T$ is the 16 -bit integer value ( 23 to 32,767 ).
FRAC1 is the numerator of the primary modulus ( 0 to $33,554,431$ ).
FRAC2 is the numerator of the 14-bit auxiliary modulus ( 0 to 16,383 ).
MOD2 is a programmable, 14-bit auxiliary fractional modulus ( 2 to 16,383 ).
MOD1 is a 25-bit primary modulus with a fixed value of $2^{25}$ $=33,554,432$.

Figure 90. N Counter Functional Block Diagram

Figure 91. Reference Input Path Block Diagram

These calculations result in a low frequency resolution with no residual frequency error. To apply the previous equation, perform the following steps:

1. Calculate N by dividing $\mathrm{fvco} / \mathrm{f}_{\text {prd. }}$. The integer value of this number forms INT.
2. Subtract INT from the full N value.
3. Multiply the remainder by $2^{25}$. The integer value of this number forms FRAC1.
4. Calculate MOD2 based on the channel spacing ( $\mathrm{f}_{\mathrm{CHSP}}$ ) by using the following equation:

$$
M O D 2=\left(f_{P F D} /\left(\operatorname{GCD}\left(f_{P F D}, f_{C H S P}\right)\right)\right)
$$

where:
$f_{\text {CHSP }}$ is the desired channel spacing frequency. $\operatorname{GCD}\left(f_{\text {PFD }}, f_{C H S P}\right)$ is the greatest common divisor of the PFD frequency and the channel spacing frequency.
5. Calculate FRAC2 by using the following equation:

$$
F R A C 2=\left((N-I N T) \times 2^{25}-\text { FRAC1 }\right) \times M O D 2
$$

The FRAC2 and MOD2 fraction result in outputs with zero frequency error for channel spacing when the following is true:

$$
\left(f_{\text {PFD }} /\left(\operatorname{GCD}\left(f_{\text {PFD }}, f_{C H S P}\right)\right)=M O D 2<16,383\right.
$$

If zero frequency error is not required, the MOD1 and MOD2 denominators operate together to create a 39bit resolution modulus.

## INT N MODE

When FRAC1 and FRAC2 are equal to 0 , the synthesizer operates in Integer N mode. It is recommended to set the SD_PD bit (Register 0x02B, Bit 0) to 1 to disable the $\Sigma-\Delta$ modulators (SDMs), which improves the in band phase noise and reduces any additional $\Sigma$ - $\Delta$ noise.

## PHASE FREQUENCY DETECTOR AND CHARGE PUMP

The phase frequency detector takes inputs from the $R$ counter and N counter to produce an output that is proportional to the phase and frequency differences between these counters. This proportional information is then output to a charge pump circuit that generates current to drive an external loop filter that is then used to appropriately increase or decrease the VTUNE tuning voltage.
Figure 92 shows a simplified schematic of the phase frequency detector and charge pump. Note that the phase frequency detector includes a fixed delay element that is used to ensure that there is no dead zone in the phase frequency detector transfer function for consistent reference spur levels.

Figure 92. Phase Frequency Detector and Charge Pump Simplified Schematic

## LOOP FILTER

Defining a loop filter for a PLL is dependent on several dynamics, such as the $\mathrm{f}_{\text {PFD }}$, the N counter value, the Kvco, and the selected charge pump current (IcP). A higher fepd has the advantage of lowering in band phase noise performance at the expense of integer boundary spur levels when operating in fractional-N mode. Consequently, a lower f fFD can allow the PLL to operate in integer N mode, which can eliminate integer boundary spurs at the expense of higher in band phase noise performance. Given the trade-offs, care must be taken with frequency planning and $\mathrm{f}_{\text {PFD }}$ selection to ensure the appropriate in band phase noise performance is met with acceptable spur levels for the end application.
The loop filter, as implemented using one of the ADMV4530 evaluation boards (see the Ordering Guide section), is a third-order passive filter, as shown in Figure 93. The filter is designed with the following simulation input parameters: $\mathrm{f}_{\text {PFD }}$ $=100 \mathrm{MHz}, \mathrm{Kvco}=155 \mathrm{MHz} / \mathrm{V}$, fvco $=15 \mathrm{GHz}$, and $\mathrm{I}_{\mathrm{cP}}=4.2$ mA . The resulting loop filter bandwidth and phase margin are 540 kHz and $55^{\circ}$, respectively, for the following component values: $\mathrm{C} 1=150 \mathrm{pF}, \mathrm{C} 2=15 \mathrm{nF}, \mathrm{C} 3=20 \mathrm{pF}, \mathrm{C} 4=$ do not install (DNI), R1 $=910 \Omega, \mathrm{R} 2=910 \Omega$, and $\mathrm{R} 3=0 \Omega$. For additional guidance with loop filter simulations on the ADMV4530, contact Analog Devices for Technical Support.

Figure 93. Recommended Loop Filter

## CHARGE PUMP CURRENT SETUP

For a specifically designed loop filter, set the I ${ }_{C P}$ by adjusting the CP_CURRENT value in Bits[7:4], Register 0x01E. Calculate $I_{C P}$ by using the following the equation:

$$
I_{C P}=\left(C P_{-} C U R R E N T+1\right) \times 350 \mu \mathrm{~A}
$$

where $C P_{-}$CURRENT is an integer value ( 0 to 15 ).
The default value for a 100 MHz fpFD for CP_CURRENT $=11$, which yields a current of 4.2 mA . The applicable range is 0.35 mA to 5.6 mA , with 0.35 mA steps.

To change the $f_{\text {PFD }}$, if no change has been made to the existing loop filter components, it is recommended to scale $\mathrm{I}_{\mathrm{CP}}$ by using the following equation:

$$
I_{C P(N E W)}=\frac{I_{C P(D E F A U L T)} \times f_{\text {PFD }(D E F A U L T)}}{f_{\text {PFD }(N E W)}}
$$

where:
$I_{C P(N E W)}$ is the new desired $I_{\text {cp. }}$
$I_{C P}$ (DEFAULT) is the default Icp.
$f_{\text {PFD (DEFAULT }}$ is the default frpd.
$f_{\text {PFD (NEW) }}$ is the new desired $\mathrm{f}_{\text {PFD }}$.
When ICP (NEW) is obtained, the CP_CURRENT value in Bits[7:4], Register 0x01E, can be updated by using the following rounding function:

$$
C P_{-} C U R R E N T=\text { ROUND }\left(\frac{I_{C P(N E W)}}{350 \mu \mathrm{~A}}\right)-1
$$

where ROUND is the mathematical round function.

## BLEED CURRENT (CP_BLEED) SETUP

The charge pump includes a binary scaled bleed current (Ibleed) that is set by using the CP_BLEED value in Register $0 \times 026$. The bleed current introduces a slight phase offset in the phase frequency detector to improve integer boundary spurs and phase noise when operating in fractional- N mode. To enable the bleed current for fractional-N mode, set CP_BLEED_EN = 1 (Register 0x027, Bit 3). For integer mode, CP_BLEED_EN must be set to 0 .
Generally, the optimum bleed current value is 115 (431.25 $\mu \mathrm{A}$ ), and this value provides optimal performance for most applications. However, there can be additional performance improvements by empirically determining the appropriate bleed current value from the actual measurements for the intended application. The applicable range is $0 \mu \mathrm{~A}$ to 956.25 $\mu \mathrm{A}$ with $3.75 \mu \mathrm{~A}$ steps.

$$
I_{B L E E D}=C P_{-} B L E E D \times 3.75 \mu \mathrm{~A}
$$

where $C P_{\_} B L E E D$ is an integer value ( 0 to 255 ).

Figure 94 shows an example of 100 kHz offset phase noise vs. CP_BLEED.

Figure 94. 100 kHz Offset Phase Noise vs. CP_BLEED, LO Frequency $=29.995 \mathrm{GHz}, C P_{-}$CURRENT $=4.2 \mathrm{~mA}$
Figure 95 is an example of 100 kHz offset phase noise vs. LO frequency with a CP_BLEED value of $115(431.25 \mu \mathrm{~A})$. The CP_CURRENT was 4.2 mA and the LO frequency step size was 10 MHz . At each integer boundary, the CP_BLEED was disabled, resulting in approximately $-1 \mathrm{dBc} / \mathrm{Hz}$ improvement.

Figure 95. 100 kHz Offset Phase Noise vs. LO Frequency, CP_BLEED $=115$, CP_CURRENT $=4.2 \mathrm{~mA}$

## MUXOUT

The output multiplexer on the ADMV4530 allows the user to access various internal signals on the chip. The MUXOUT bit field (Register 0x020, Bits[7:4]) shown in Table 34 lists the available signals. When MUXOUT_SEL (Register 0x20, Bit 3) is set to 1 , the MUXOUT signal is present on the SDO output pin. Otherwise, the SDO pin is configured for SPI data output.

## DIGITAL LOCK DETECT

A digital lock detect function is available on the SDO pin when both the MUXOUT and MUXOUT_SEL bits are set to 1. The digital lock detect function is also available by reading the LD_READBACK bit (Register 0x07C, Bit 0). A logic high indicates that the digital lock detect has declared the PLL is locked.
The digital lock detect function has some adjustable settings in Register 0x027 and Register 0x028. The LD_BIAS and LDP bits adjust an internal precision window and the LD_COUNT bits adjust the consecutive cycle count to declare PLL lock. It is recommended to keep the settings listed in the register map. For special applications, contact Analog Devices Technical Support for guidance on adjusting these settings.

## VCO AUTOCALIBRATION

The internal VCO uses an internal autocalibration routine that optimizes the VCO settings for a particular frequency and allows the PLL to lock in approximately $100 \mu$ s after the lower portion of the N counter integer value (Register $0 \times 010$ ) is programmed. For nominal applications, maintain the autocalibration default values in the register map (Register 0x030 to Register 0x034).
For applications where it is desirable to bypass the autocalibration routine, there are two necessary procedures. First, generate a lookup table of the resultant VCO calibration data (core and band parameters) for each desired VCO frequency. Second, bypass the autocalibration routine and manually write the lookup table values. Generate a new table for every chip because each chip is unique.

## VCO CALIBRATION DATA READ BACK

To read back the VCO calibration data, load the required registers, let the device lock using autocalibration, and read the VCO parameters for each frequency. It is important to ensure that autocalibration has completed before readback. Reading back values before autocalibration has completed results in incorrect values being read.

The bits used for read back include the following:

- Register 0x033, Bits[7:5], VCO_FSM_READBACK
- Register 0x06E, Bits[4:0], VCO_DATA_READBACK
- Register 0x06F, Bit 0, VCO_DATA_READBACK

The VCO_FSM_READBACK bits set what data is sent to the VCO_DATA_READBACK bits.
To read the VCO parameters, take the following steps:

1. Program the device to lock at the desired frequency by using the autocalibration feature. Users must wait for the device to lock.
2. Set VCO_FSM_READBACK = 1 to allow readback of the VCO band and the core.
3. Read Register 0x06F, Bit 0 to read back the current VCO core. The ADMV4530 has only one VCO core. Therefore, this value must always be 1 .
4. Read Register 0x06E, Bits[4:0] to read back the VCO band.

Repeat Step 1 through Step 4 for each required frequency to build a lookup table of values.

## VCO CALIBRATION DATA MANUAL WRITING

The VCO parameters for each required frequency force the device to the target frequency core and band without the use of autocalibration.
The bits used for writing to the VCO parameters include the following:

- Register 0x034, Bits[7:5], VCO_FSM_TEST_MODES
- Register 0x037, Bits[7:0], SI_BAND_SEL
- Register 0x038, Bits[7:4], SI_VCO_SEL

To write the VCO parameters, take the following steps:

1. At power-up, set up the serial port interface and initialize the device as necessary for normal operation.
2. Set AUTOCAL_EN $=0$ (Register $0 \times 012$, Bit 6) to disable autocalibration.
3. Set VCO_FSM_TEST_MODES $=010$ to overwrite the VCO core and band.
4. Program the registers, except Register 0x010, as required for the target frequency. This step is frequency dependent.
5. Set SI_VCO_SEL = 1. Even though the ADMV4530 has only one VCO core, it is still necessary to program this bit because this bit tells the internal finite state machine to enable the VCO.
6. Set SI_BAND_SEL to the desired band from the previously generated lookup table.
7. Write to Register $0 \times 010$. When this register is written to, the device locks to the new frequency.
Repeat Step 4 through Step 7 as required for setting the appropriate VCO frequency.

## AUTOCALIBRATION LOCK TIME

The PLL lock time divides into a number of settings. The total lock time for changing frequencies is the sum of three separate times: synthesizer lock, VCO band selection, and PLL settling.

## SYNTHESIZER LOCK TIMEOUT

The synthesizer lock timeout ensures that the VCO calibration digital-to-analog converter (DAC), which forces the VCO tune voltage ( $\mathrm{V}_{\text {vTUNE }}$ ), has settled to a steady value for the band select circuitry. The SYNTH_LOCK_TIMEOUT and the TIMEOUT bits select the length of time the DAC is allowed to settle to the final voltage before the VCO calibration process continues to the next phase (VCO band selection). The PFD frequency is the clock for this logic, and the duration is set by using the following equation:
(SYNTH_LOCK_TIMEOUT $\times 1024+$ TIMEOUT) $/ f_{\text {PFD }}$ where:
SYNTH_LOCK_TIMEOUT is programmed in Bits[4:0], Register 0x033.
TIMEOUT is programmed in Bits[7:0], Register 0x031 and Bits[1:0], Register 0x032.
The calculated time must be greater than or equal to $20 \mu \mathrm{~s}$.
For the SYNTH_LOCK_TIMEOUT bits, the minimum value is 2 , and the maximum value is 31 .

For TIMEOUT, the minimum value is 2 , and the maximum value is 1023.

## VCO BAND SELECTION TIME

Use the VCO_BAND_DIV bits (Bits[7:0], Register 0x030) and the fPFD to generate the VCO band selection clock ( $\mathrm{f}_{\mathrm{BSC}}$ ) as follows:

$$
f_{B S C}=\left(f_{\text {PFD }} / V C O \_B A N D \_D I V\right)
$$

The calculated frequency must be less than 2.4 MHz .
Note that 16 clock cycles are required for one VCO core and band calibration step and the total band selection process takes 11 steps, resulting in the following equation:

$$
11 \times\left(16 \times V C O \_B A N D \_D I V / f_{P F D}\right)
$$

The minimum value for VCO_BAND_DIV is 1, and the maximum value is 255 .

## PLL SETTLING TIME

The time taken for the loop to settle is inversely proportional to the low-pass filter bandwidth.

## CHIP TEMPERATURE READ BACK

Chip temperature readback can provide information regarding system temperature, which is useful for system compensation.

The ADMV4530 includes an analog-to-digital converter (ADC) that enables reading the chip temperature. The ADC clock (ADC_CLK) is generated from the phase frequency detector clock ( $\mathrm{f}_{\mathrm{PFD}}$ ) with the following equations:

$$
A D C_{-} C L K=\frac{f_{P F D}}{\left(\left(A D C_{-} C L K_{-} D I V \times 4\right)+2\right)}
$$

where $A D C_{-} C L K_{-} D I V$ is stored in Register $0 \times 035$.
A valid reference signal is required to complete a conversion. Target 100 kHz for ADC_CLK and calculate ADC_CLK_DIV with the following equation:

$$
A D C_{-} C L K_{-} D I V=\text { ceiling }\left(\frac{\left(\left(\frac{f_{P F D}}{100,000}\right)-2\right)}{4}\right)
$$

If ADC_CLK_DIV is greater than 255, set these bits to 255.
The bits used for temperature readback are the following:

- Register 0x032, Bit 2, ADC_ENABLE
- Register 0x032, Bit 3, ADC_CONVERSION
- Register 0x033, Bits[7:5], VCO_FSM_READBACK
- Register 0x06E, Bits[7:0], VCO_DATA_READBACK[7:0]
- Register 0x073, Bit 2, ADC_CLK_DISABLE

To read back the temperature, take the following steps:

1. Set ADC_ENABLE $=1$ to enable the ADC.
2. Set ADC_CONVERSION = 1 to perform an ADC conversion.
3. Wait 16 ADC_CLK cycles.
4. Set VCO_FSM_READBACK = 101 (skip this step if it is already set).
5. Read the VCO_DATA_READBACK bits in Register 0x06E to read back the raw ADC output that corresponds to the chip temperature (RAW_TEMP).
6. Set ADC_CONVERSION $=0$ to disable the conversion.
7. Set ADC_ENABLE $=0$ to disable the ADC, which prevents any spurs generated by the ADC clock. Similarly, the ADC_CLK_DISABLE bit can disable the ADC clock.

Perform Step 1 and Step 2 separately. However, Step 6 and Step 7 can be completed together.
To calculate the approximate chip temperature in Celsius $\left({ }^{\circ} \mathrm{C}\right)$, use the following equation:

Chip Temperature $=-115^{\circ} \mathrm{C}+$ RAW_TEMP

## RF OUTPUT DRIVER

As shown in the functional block diagram (see Figure 1), the ADMV4530 incorporates two driver stages along with a voltage variable attenuator (VVA) in the RF output section of the chip. The VCTR_RF pin (Pin 4) is connected to the VVA, which adjusts the RF output gain. The voltage range for the VCTR_RF pin is 0 V to 1.8 V , with a positively sloping linear region between 0.6 V to 1.5 V , as shown in Figure 8. The typical slope within linear region is $32 \mathrm{~dB} / \mathrm{V}$.

## I/Q MODE MIXER SETUP

In baseband quadrature modulation mode, the input impedance of the baseband pins (IN, IP, QN, and QP) are $100 \Omega$ differential. These inputs can be driven with a dccoupled $100 \Omega$ differential source. IN and IP are the differential baseband I inputs, and QN and QP are the differential baseband $Q$ inputs. These inputs can operate from a common-mode voltage range of 0 V to 2.5 V . When operating in I/Q mode, program the following registers:

- Register $0 \times 100=0 \times 3 \mathrm{~A}$
- Register 0x101 $=0 \times 78$
- Register $0 \times 102=0 \times 11$
- Register 0x103 = 0x5D (for 0.5 V Vсм)
- Register $0 \times 106$ to $0 \times 109=0 \times 7 \mathrm{~F}$
- Register $0 \times 115=0 \times 88$

When $\mathrm{V}_{\text {см }}$ changes, program Register 0x103 by using the following formulas for each mode.
In I/Q mode, for V см $=0.0 \mathrm{~V}$ to 1.5 V , set
MIXER_VCM $=\operatorname{ROUND}\left(23.8 \times V_{C M}+80.7\right)$.
In $\mathrm{I} / \mathrm{Q}$ mode, for V см $=1.5 \mathrm{~V}$ to 2.5 V , set
MIXER_VCM $=$ ROUND $\left(23.8 \times V_{C M}+1.3\right)$.
The $\mathrm{I} / \mathrm{Q}$ mode default for $\mathrm{V}_{\mathrm{CM}}=0.5 \mathrm{~V}$ is MIXER_VCM $=93=$ $0 \times 5 \mathrm{D}$.

## I/Q MODE LO NULLING

To perform LO nulling in I/Q mode, apply a differential dc offset on the I and Q inputs. Note that LO nulling is a twostep process. When LO nulling is done on the I side, keep the Q side at $\mathrm{V}_{\mathrm{Cm}}$, and when LO nulling is done on the Q side, the I side must be kept at $V_{C M}$ or at the determined value in the first step. The optimal LO null is when settings from the I side and the Q side are combined. It is important to keep $V_{C M}$ constant. Therefore, when a dc offset is applied on the negative input ( $\mathrm{V}_{\text {CMN }}$ ), the same offset must be applied on the positive input ( $\mathrm{V}_{\mathrm{CMP}}$ ) in the opposite direction ( $\mathrm{V}_{\mathrm{CMP}} \pm \mathrm{dc}$ offset and $V_{\text {CMN }} \mp$ dc offset) to allow the average $V_{\text {CM }}$ to hold constant to coincide with the value programmed in Register $0 \times 103$. LO nulling at a single point is optimal at that particular frequency and temperature, and the absolute level ( dBm ) of the LO to RF feedthrough remains the same across gain settings using the VCTR_RF input.

For example, it is possible to null LO down to -50 dBm with VCTR_RF = 1.8 V , depending on the resolution of the dc offset applied and the temperature (as shown in Figure 28 and

Figure 29), where LO nulling $=29 \mathrm{GHz}$. When LO nulling $=$ 29 GHz , the LO to RF feedthrough is <-20 dBm over temperature, and the frequency range is from 28 GHz to 30 GHz .

## I/Q MODE SIDEBAND REJECTION NULLING

In I/Q mode, use Register 0x104 or Register 0x105 to perform sideband rejection nulling. Each register has 128 settings, Bits[6:0]. Single frequency nulling allows sideband rejection to null down to -45 dBc for a particular frequency. The sideband rejection degrades to -35 dBc if the frequency or temperature changes (shown in Figure 27 and Figure 30).

## IF GAIN CONTROL

As shown in the functional block diagram (see Figure 1), the ADMV4530 incorporates an IF amplifier with analog gain control. The analog voltage for this IF amplifier can either be provided by the internal AGC loop or by applying an external VCTR_IF voltage to the EXT_CAP_N (Pin 10). The voltage range for the IF amplifier gain control is 0 V to 3.3 V , with a negatively sloping linear region between 0.9 V and 2.2 V , as shown in Figure 38. The typical slope within linear region is $-32 \mathrm{~dB} / \mathrm{V}$.

## IF MODE MIXER SETUP

The ADMV4530 features the ability to upconvert a real IF input anywhere from 2 GHz to 3 GHz . When operating in IF mode program the following registers:

- Register $0 \times 100=0 \times 03$
- Register 0x101 = 0x7D
- Register $0 \times 102=0 \times 3 \mathrm{~F}$
- Register $0 \times 103=0 \times 5 B$ (this register sets $V_{\text {CM }}$ in IF mode)
- Register 0x104 to $0 \times 109=0 \times 5 F$
- Register $0 \times 115=0 \times 08$

When $V_{\text {см }}$ changes, program Register $0 \times 103$ by using the following formula:

```
MIXER_VCM = ROUND(0.3 * (128 -
TARGET_MIXER_DC_OFFSET) + 80.7)
```

where TARGET_MIXER_DC_OFFSET is the value programmed into Register 0x106 to Register 0x109.

## IF MODE LO NULLING

LO nulling is performed in IF mode in a similar fashion as in I/Q mode. However, dc offset is applied through Register 0x106 to Register 0x109. Use Register 0x106 and Register $0 \times 107$ to force a dc offset on the I side, and use Register 0x108 and Register 0x109 to force a dc offset on the $Q$ side. It is important to sweep the I and Q registers simultaneously in opposite direction so that the following are true:
(MIXER_DC_OFFSET_IP + MIXER_DC_OFFSET_IN)/2 = TARGET_MIXER_DC_OFFSET
$\left(M I X E R \_D C_{-} O F F S E T \_Q P+M I X E R \_D C_{-} O F F S E T \_Q N\right) / 2=$ TARGET_MIXER_DC_OFFSET
As in I/Q mode, LO nulling is two-step process. When LO nulling on the I side, keep the $Q$ side at the TARGET_MIXER_DC_OFFSET. When LO nulling on the Q side, keep the I side at the TARGET_MIXER_DC_OFFSET, or at the determined value from the first step. The optimal null is achieved when both settings are combined. The recommended TARGET_MIXER_DC_OFFSET value is

95 decimal ( $0 x 5 \mathrm{~F}$ ). It is recommended to keep the TARGET_MIXER_DC_OFFSET above 63. The MIXER_DC_OFFSET range for Register 0x106 to Register $0 \times 109$ is from 63 decimal to 127 decimal. The LO to RF feedthrough improves to approximately -30 dB following this procedure. When the LO is nulled at a single frequency and temperature, the LO to RF feedthrough is less than -40 dBc , and the LO to RF feedthrough is less than -25 dBc across frequency and temperature, as shown in Figure 57.

## IF MODE SIDEBAND REJECTION NULLING

In IF mode, use Register 0x104 or Register 0x105 to perform sideband rejection nulling. Each register has 128 settings, Bits[6:0]. Single frequency nulling allows sideband rejection to null down to -50 dBc for a particular frequency. If the operating frequency or temperature changes, sideband rejection nulling degrades. When sideband rejection is nulled at 29 GHz , it is less than -30 dBc over temperature and the frequency range is from 28 GHz to 30 GHz (as shown in Figure 56).

## APPLICATIONS INFORMATION

## IF AGC CONFIGURATION

The ADMV4530 includes an AGC circuit on the IF input port. The four bit fields that control the functionality of this AGC follow:

1. AGC_EN (Register 0x101)
2. AGC_EN_OVERRIDE (Register 0x102)
3. IF_DET_EN_OVERRIDE (Register 0x102)
4. DET_RANGE (Register 0x10C)
5. AGC_VREF_GEN (Register 0x10D)

The AGC_EN bit enables or disables the AGC that is only truly enabled when in power-down mode. The AGC_EN_OVERRIDE and IF_DET_EN_OVERRIDE bits enable the AGC and detector regardless of the power-down mode.
The DET_RANGE bit field selects the appropriate range for the internal power detector, and the AGC_VREF_GEN bit field determines the voltage reference set point for the AGC.
Figure 96 shows an example of the output power vs. the input power level for various settings of DET_RANGE and AGC_VREF_GEN. The first number in the Figure 96 legend is the DET_RANGE setting (decimal value), and the second number in the Figure 96 legend is the AGC_VREF_GEN setting (decimal value).

Figure 96. Power Sweep for Various AGC Settings

Figure 97 shows the output power given a -20 dBm input IF signal and sweeping the AGC voltage reference set point for various DET_RANGE settings.

Figure 97. AGC Voltage Reference Sweep
When AGC is enabled, the AGC voltage needed for the IF gain control is accessible on the EXT_CAP_N pin (Pin 10). When the AGC is disabled, this pin functions as an input for the IF amplifier gain control.

## ERROR VECTOR MAGNITUDE PERFORMANCE

The error vector magnitude performance of the ADMV4530 is measured at an RF frequency of 29.98 GHz (fractional mode, phase noise adjusted as shown in Figure 94) and an RF frequency of 30 GHz (integer mode) with a single 12 MHz , 8 quadrature phase shifting keying (QPSK) carrier in I/Q mode, 0 Hz offset, 0.2 roll-off factor, and LO and sideband rejection nulled. The measurement was performed at $\mathrm{T}_{\mathrm{A}}=$ $25^{\circ} \mathrm{C}$.
Figure 98 shows the transmitter error vector magnitude vs. the output power. The transmitter has an approximately $3 \%$ error vector magnitude with an output power of 12 dBm .

Figure 98. Error Vector Magnitude vs. Output Power, 8 QPSK
Modulation, 12 MHz Bandwidth

## PLL LOCK TIME IN IF AND I/Q MODE

Using the recommended autocalibration setup described in the VCO Autocalibration section, the typical autocalibration lock time is shown in Figure 99. These results reflect a VCO band selection clock ( $\mathrm{f}_{\mathrm{BSC}}$ ) $=4 \mathrm{MHz}$.

Figure 99. LO Frequency vs. Time, REF_IN Frequency $=200 \mathrm{MHz}, f_{B S C}=$ 4 MHz

## POWER UP AND DOWN

The ADMV4530 includes a power-down (PD) pin that when enabled turns off the mixer and output driver section of the chip but keeps the PLL and VCO active. For applications where a fast power-up time is required, this standby mode is useful for muting the RF output signal while keeping the PLL locked. Figure 100 shows the typical response time of the PD pin.

Figure 100. Relative Output Level vs. Time, Power-Up and PowerDown

The chip can be set to its lowest power state by disabling the bias for the PLL, VCO, and RF sections. To accomplish setting the chip to its lowest power state, enable the following bits:

- PLL_PD, Register 0x01E, Bit 2
- VCO_PD, Register 0x027, Bit 2
- RF_BIAS_PD, Register 0x100, Bit 7

When exiting the lowest power state and bringing the device back to nominal operating conditions, the PLL must be relocked by updating Register 0x010. Table 8 details the typical power consumption for nominal, standby, and low power conditions.

Table 8. Typical Power Consumption at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$

| State | Power (W) | Test Conditions/Comments |
| :--- | :--- | :--- |
| Nominal |  | Maximum gain |
| I/Q Mode | 1.8 |  |
| IF Mode | 2.5 | PD pin high |
| Standby |  |  |
| I/Q Mode | 0.7 |  |
| IF Mode | 1.4 | PD pin high, PLL, VCO, and RF disabled |
| Low Power | 0.2 |  |

## REGISTER SUMMARY

N/A means not applicable, R means read, and R/W means read/write.
Table 9. Register Summary

| Reg <br> (Hex) | Name | Bits | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 | Rese t | Recommende d | $\begin{aligned} & \hline \mathbf{R} / \\ & \mathbf{W} \end{aligned}$ |
