

# ADP1829 and ADP1821 Reference Design

Preliminary Technical Data

FCDC 00081

## FEATURES

**Five Output Voltages: 1.2 V, 1.8 V, 3.3 V, 5 V, 12 V**

**Output Current: 1 A to 4.5 A**

**Input voltage: 15.2-16.8 V**

**Ripple 50 mV ppk**

**Transient step  $\pm 5\%$ , 50% max load**

## ADP1829 AND ADP1821 REFERENCE DESIGN DESCRIPTION

This ADP1829 and ADP1821 Reference Design uses 15.2 V to 16.8 V for the input voltage. The output voltages and currents are as follows:

- $V_{OUT1} = 1.2 \text{ V}$  with a maximum output current of 3.5 A,
- $V_{OUT2} = 1.8 \text{ V}$  with a maximum output current of 1.4 A,
- $V_{OUT3} = 3.3 \text{ V}$  with a maximum output current of 2.2 A,
- $V_{OUT4} = 5.0 \text{ V}$  with a maximum output current of 2.3 A,
- $V_{OUT5} = 12 \text{ V}$  with a maximum output current of 1.2 A.

Design criteria are for coincidental tracking of  $V_{OUT1}$ ,  $V_{OUT2}$  and  $V_{OUT3}$  with  $V_{OUT4}$  for both turn on and turn off. The ripple and transient assumptions are 50 mV peak to peak voltage ripple and 5% deviation due to 50% instantaneous load step. The switching frequency is fixed at 300 kHz for  $V_{OUT1}$ ,  $V_{OUT2}$ ,  $V_{OUT3}$ ,  $V_{OUT4}$  and  $V_{OUT5}$ .

## REVISION HISTORY

10/17/2007—Revision 0: Initial Version

10/19/2007—Revision 1: Updated Efficiency graphs to show comparison of Rohm SP8K3 dual. Added Sgnd to schematic.

## GENERAL DESCRIPTION

### **ADP1829**

The ADP1829 is a versatile, dual output, interleaved, synchronous PWM buck controller that generates two independent outputs from an input voltage of 3.0 V to 18 V. Each channel can be configured to provide output voltage from 0.6V to 85% of the input voltage. The two channels operate 180° out of phase, which reduces the current stress on the input capacitor and allows the use of a smaller and lower cost input capacitor.

The ADP1829 operates at a pin-selectable fixed switching frequency of either 300 kHz or 600 kHz. For some noise sensitive applications, it can also be synchronized to an external clock to achieve switching frequency between 300 kHz and 1 MHz. The switching frequency chosen is 300 kHz to get good efficiency over a wide range of input and output conditions.

The ADP1829 includes an adjustable soft start to limit input inrush current, voltage tracking for sequencing or DDR termination, independent power-good output, and a power enable pin. It also provides current-limit and short-circuit protection by sensing the voltage on the synchronous MOSFET.

### **ADP1821**

The ADP1821 is a versatile and inexpensive, synchronous, pulse width-modulated (PWM), voltage-mode, step-down controller. It drives an all N-channel power stage to regulate an output voltage as low as 0.6 V. The ADP1821 can be configured to provide output voltages from 0.6 V to 85% of the input voltage and is sized to handle large MOSFETs for point-of-load regulators. The ADP1821 is well suited for a wide range of high power applications, such as DSP and processor core power in telecom, medical imaging, high performance servers, and industrial applications. It operates from a 3.0 V to 5.5 V supply with a power input voltage ranging from 1.0 V to 24 V. The ADP1821 operates at a pin-selectable, fixed switching frequency of either 300 kHz or 600 kHz, minimizing external component size and cost. For noise-sensitive applications, it can be synchronized to an external clock to achieve switching frequencies between 300 kHz and 1.2 MHz. The ADP1821 includes soft start protection to limit the inrush current from the input supply during startup, reverse current protection during soft start for precharged outputs, as well as a unique adjustable lossless current-limit scheme utilizing external MOSFET sensing. The ADP1821 operates over the -40°C to +85°C temperature range and is available in a 16-lead QSOP.

## NOTES

Reference designators shown on the schematic but not listed on the Bill of Materials are place holders for possible design adjustments (snubbers, additional decoupling capacitors and clamp diodes). These components should be put in the layout, but not populated unless after testing it is deemed necessary.

If a different number, or different type of output capacitors are used on the switching outputs the loop compensation components may need adjustment.

Efficiency calculations are estimates and are not verified in actual hardware. Any shoot-through caused by dV/dt induced turn on of the lowside FET is not included in efficiency (likely present in Rohm low side FETs).

FETs with reference designators ending in a letter (i.e. a, b, or c) are connected in parallel with the other FETs of the same reference designator prefix. These FETs should be placed physically close together and have large power planes connecting all the drains together and large power planes connecting all the sources together. Gate drive resistors may be used if there is concern about possible paralleling issues.

Ground symbols with an S designator should be connected together with one small plane and tied to the power ground plane at one point near the IC. Each IC should have its own S ground pour.
