The NX2423 is a two-phase PWM controller with integrated FET driver designed for low voltage high current application. The two phase synchronous buck converter offers ripple cancelation for both input and output. The NX2423 uses differential remote sensing using either current sense resistor or inductor DCR sensing to achieve accurate current matching between the two channels. Differential sensing eliminates the error caused by PCB board trace resistance that otherwise presents when using a single ended voltage sensing.
In addition the NX2423 offers high drive current capability especially for keeping the synchronous MOSFET off during SW node transition, can provide regulated 5 V to IC biasing and drivers via 5 V bias regulator, allows the slave channel on and off via EN2_B pin while the main channel is working. Other features: PGOOD output, programmable switching frequency and hiccup current limiting circuitry.

Differential inductor DCR sensing eliminates the problem with layout parasitic
5 V bias regulator available
Low Impedance On-board Drivers
Hiccup current limit and IOUT indication
Power Good for power sequencing
EN2_B pin allows the slave channel on and off while the master channel is working
Programmable frequency
Prebias start up
OVP without negative spike at output Selectable between internal and external reference Internal Schottky diode from PVCC to BST
Pb-free and RoHS compliant
APPLICATIONS
Graphic card High Current Vcore Supply
High Current on board DC to DC converter applications

TYPICAL APPLICATION

Figure1 - Typical application of NX2423
ORDERING INFORMATION

| Device | Temperature | Package | Frequency | Pb-Free |
| :---: | :---: | :---: | :---: | :---: |
| NX2423CMTR | 0 to $70^{\circ} \mathrm{C}$ | MLPQ $4 \times 4-24 \mathrm{~L}$ | 50 kHz to 1 MHz | Yes |

## ABSOLUTE MAXIMUM RATINGS

Vcc to PGND \& BST to SW voltage -0.3 V to 6.5 V
BST to PGND Voltage -0.3 V to 35 V
SW to PGND -2 V to 35 V
All other pins -0.3 V to 6.5 V
Storage Temperature Range $-65^{\circ} \mathrm{C}$ To $150^{\circ} \mathrm{C}$
Operating Junction Temperature Range ............... $-40^{\circ} \mathrm{C}$ To $125^{\circ} \mathrm{C}$
Lead temperature(Soldering 5s)
$260^{\circ} \mathrm{C}$
CAUTION: Stresses above those listed in "ABSOLUTE MAXIMUM RATINGS", may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

## ELECTRICAL SPECIFICATIONS

Unless otherwise specified, these specifications apply over $5 \mathrm{Vcc}=5 \mathrm{~V}, \mathrm{PV} \mathrm{Vc}=5 \mathrm{~V}, \mathrm{~V}_{\mathrm{BST}}-\mathrm{V}_{\mathrm{sw}}=5 \mathrm{~V}$, EN2_B=GND, and $T_{A}=0$ to $70^{\circ} \mathrm{C}$. Typical values refer to $T_{A}=25^{\circ} \mathrm{C}$. Low duty cycle pulse testing is used which keeps junction and case temperatures equal to the ambient temperature.

## PIN DESCRIPTIONS

| SYMBOL | PIN DESCRIPTION |
| :---: | :---: |
| HDRV1 | High side gate driver for Channel 1. |
| BST1 | Bootstrap supply for Channel 1. |
| 5VCC | IC's supply voltage. This pin biases the internal logic circuits. A minimum $1 u F$ ceramic capacitor is recommended to connect from this pin to ground plane. |
| AGND | Controller analog ground pin. |
| EN2_B | This pin is used to startup or shutdown the channel 2 only while 5 VCC and REFIN is ready. For two phase opeartion, EN2_B is preferred to be tied to GND. For one phase opeartion, EN2_B is preferred to be tied to 5VCC. During the operation, it is not recommended to change EN2_B voltage. |
| CS+1 | Positive input of the channel 1 differential current sense amplifiers. It is connected directly to the RC junction of the respective phase's output inductor. |
| CS-1 | Negative input of the channel 1 differential current sense amplifiers. It is connected directly to the negative side of the respective phase's output inductor. |
| CS-2 | Negative input of the channel 2 differential current sense amplifiers. It is connected directly to the negative side of the respective phase's output inductor. |
| CS+2 | Positive input of the channel 2 differential current sense amplifiers. It is connected directly to the RC junction of the respective phase's output inductor. |
| IOUT/IMAX | This pin indicates average output current level and sets OCP threshold using a resistor from this pin to ground. A no more than 1 nF ceramic capacitor is recommended to connect this pin to ground plane to filter the noise on this pin. |
| RT | This pin programs the internal oscillator frequency using a resistor from this pin to ground. |
| VCOMP | This is the output pin of the error amplifier. |
| FB | This pin is the error amplifier inverting input. It is connected to the output voltage via a voltage divider. |
| CSCOMP | The output of the transconductance op amp for current balance circuit. An external RC is connected from this pin to GND to stabilize the current loop. |
| REFIN | External reference input. If pull-up to $>4.5 \mathrm{~V}$, internal reference is used. If driven by an external voltage ranged from 0.4 V to 2.5 V , external reference is used with slew rate following SS rate. If REFIN is below 0.4 V , device is disabled. |
| INREFOUT/ POK | This pin has dual functions. When FB pin is below $75 \%$ of internal 0.6 V reference, this pin is held low. When FB reaches above this threshold, this pin is tied to an internal 1.25 V reference, allowing it to be used as a reference for any external op amp circuitry as well as an indicator of power OK. This pin can not be connected directly to an output capacitor. An RC network is needed which also provides a slow ramp up of the reference for the external op amp. |

| SYMBOL | Bootstrap supply for Channel 2. |
| :---: | :--- |
| HST2 | High side gate driver for Channel 2. |
| SW2 | Switch node for Channel2. |
| LDRV2 | Low side gate driver for Channel 2. |
| PVCC | This pin provide the supply voltage for the lower MOSFET drivers. This pin provide <br> the supply voltage for the lower MOSFET drivers. A high frequency ceramic 1uF <br> must be placed close to this pin and tied to PGND to provide peak current <br> needed for low side MOSFETs. |
| SDRV1 | Low side gate driver for Channel 1. |
| SW1 | Switch node for Channel 1. |
| PGND | This is the ground connection for the power stage of the controller. |
| The output of the 5V regulator controller that drives a low current low cost exter- |  |
| nal BIPOLAR transistor or an external MOSFET to regulate the voltage at Vcc pin |  |
| derived from BUS voltage. A resistor with value from 1k to 10k is used to connect |  |
| VCCDRV and VBUS. Pulling down VCCDRV is used to disable chip in NX2423 |  |
| application. |  |

## BLOCK DIAGRAM

Figure 2 - Block diagram of NX2423

## APPLICATION INFORMATION

Symbol Used In Application Information:
Vin - Input voltage
Vout - Output voltage
lout - Output current
$\Delta V_{\text {RIPPLE }}$ - Output voltage ripple
Fs - Operation frequency for each channel
$\Delta I_{\text {RIPPLE }}$ - Inductor current ripple

## Design Example

The following is typical application for NX2423.

```
VIN = 12V
VOUT=1.2V
lout=50A
lout_max=60A
\(\Delta V_{\text {RIPPLE }}<=12 \mathrm{mV}\)
\(\Delta V_{\text {Droop }}=120 \mathrm{mV}\) @30A step
Fs \(=400 \mathrm{kHz}\)
Phase number \(\mathrm{N}=2\)
```

## Output Inductor Selection

The selection of inductor value is based on inductor ripple current, power rating, working frequency and efficiency. Larger inductor value normally means smaller ripple current. However if the inductance is chosen too large, it brings slow response and lower efficiency. Usually the ripple current ranges from $20 \%$ to $40 \%$ of the output current. This is a design freedom which can be decided by design engineer according to various application requirements. The inductor value can be calculated by using the following equations:

$$
\begin{align*}
& \mathrm{L}_{\text {OUT }}=\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{\text {OUT }}}{\Delta \mathrm{I}_{\text {RIPPLE }}} \times \frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {IN }}} \times \frac{1}{\mathrm{~F}_{\mathrm{S}}} \\
& \Delta \mathrm{I}_{\text {RIPPLE }}=\mathrm{k} \times \frac{\mathrm{I}_{\text {OUTPUT }}}{\mathrm{N}} \tag{1}
\end{align*}
$$

where k is between 0.2 to 0.4 .
Select $k=0.2$, then

$$
\mathrm{L}_{\text {OUT }}=\frac{12 \mathrm{~V}-1.2 \mathrm{~V}}{0.2 \times \frac{50 \mathrm{~A}}{2}} \times \frac{1.2 \mathrm{~V}}{12 \mathrm{~V}} \times \frac{1}{400 \mathrm{kHz}}
$$

$$
\mathrm{L}_{\text {out }}=0.54 \mathrm{uH}
$$

Choose inductor from Vishay IHLP_5050FD-01 with $\mathrm{L}=0.68 \mathrm{uH}$ DCR $=1.4 \mathrm{~m} \Omega$.

Current Ripple is recalculated as

$$
\begin{align*}
\Delta \mathrm{I}_{\text {RIPPLE }} & =\frac{\mathrm{V}_{\text {IN }}-\mathrm{V}_{\text {OUT }}}{\mathrm{L}_{\text {OUT }}} \times \frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {IN }}} \times \frac{1}{\mathrm{~F}_{\mathrm{S}}} \\
& =\frac{12 \mathrm{~V}-1.2 \mathrm{~V}}{0.68 \mathrm{uH}} \times \frac{1.2 \mathrm{~V}}{12 \mathrm{~V}} \times \frac{1}{400 \mathrm{kHz}}=3.97 \mathrm{~A} \tag{2}
\end{align*}
$$

## Output Capacitor Selection

Output capacitor value is basically decided by the output voltage ripple, capacitor RMS current rating and load transient.

## Based on Voltage Ripple

For electrolytic, POSCAP bulk capacitor, the ESR (equivalent series resistance) and inductor current typically determines the output voltage ripple.

$$
\begin{equation*}
\mathrm{ESR}_{\text {desire }}=\frac{\Delta \mathrm{V}_{\text {RIPPLE }}}{\Delta \mathrm{I}_{\mathrm{RPPLLE}}}=\frac{12 \mathrm{mV}}{3.97 \mathrm{~A}}=3.022 \mathrm{~m} \Omega \tag{3}
\end{equation*}
$$

If low ESR is required, for most applications, multiple capacitors in parallel are better than a big capacitor. For example, for 12 mV output ripple, SANYO OSCON capacitors 2R5SEPC1000MX(1000uF 7m $\Omega$ ) are chosen.

$$
\begin{equation*}
\mathrm{N}=\frac{\mathrm{ESR}}{\mathrm{E} \times \Delta \mathrm{I}_{\mathrm{RIPPLE}}} \underset{\Delta \mathrm{~V}_{\mathrm{RIPPLE}}}{ } \tag{4}
\end{equation*}
$$

Number of Capacitor is calculated as

$$
\mathrm{N}=\frac{7 \mathrm{~m} \Omega \times 3.97 \mathrm{~A}}{12 \mathrm{mV}}
$$

$\mathrm{N}=2.3$
For ceramic capacitor, the current ripple is determined by the number of capacitor instead of ESR

$$
\begin{equation*}
\mathrm{C}_{\text {OUT }}=\frac{\Delta \mathrm{I}_{\mathrm{RIPPLE}}}{8 \times \mathrm{F}_{\mathrm{S}} \times \Delta \mathrm{V}_{\mathrm{RIPPLE}}} \tag{5}
\end{equation*}
$$

Typically, the calculated capacitance is so small that the output voltage droop during the transient can not meet the spec although ripple is small.

## Based On Transient Requirement

Typically, the output voltage droop during transient is specified as:
$\Delta \mathrm{V}_{\text {DROop }}<\Delta \mathrm{V}_{\text {TRAN }} @$ step load $\Delta \mathrm{I}_{\text {STEP }}$
During the transient, the voltage droop during the transient is composed of two sections. One Section is dependent on the ESR of capacitor, the other section is a function of the inductor, output capacitance as well as input, output voltage. For example, overshoot caused by $\Delta$ Istep transient load which is from high load to low load, can be estimated as the following equation, if assuming the bandwidth of system is high enough.

$$
\begin{equation*}
\Delta \mathrm{V}_{\text {overshoot }}=\mathrm{ESR} \times \Delta \mathrm{I}_{\text {step }}+\frac{\mathrm{V}_{\text {OUT }}}{2 \times \mathrm{L} \times \mathrm{C}_{\text {out }}} \times \tau^{2} \tag{6}
\end{equation*}
$$

where $\tau$ is the a function of capacitor, etc.

$$
\tau=\left\{\begin{array}{l}
0 \text { if } \mathrm{L}_{\mathrm{EFF}} \leq \mathrm{L}_{\text {cit }}  \tag{7}\\
\frac{\mathrm{L}_{\mathrm{EFF}} \times \Delta \mathrm{I}_{\text {sep }}}{\mathrm{V}_{\text {out }}}-\mathrm{ESR} \times \mathrm{C}_{\text {out }} \quad \text { if } \quad \mathrm{L}_{\text {erF }} \geq \mathrm{L}_{\text {crit }}
\end{array}\right.
$$

where

$$
\begin{align*}
& \mathrm{L}_{\text {EFF }}=\frac{\mathrm{L}_{\text {OUT }}}{\mathrm{N}}=\frac{0.68 \mathrm{uH}}{2}=0.34 \mathrm{uH} \\
& \mathrm{~L}_{\text {crit }}=\frac{E S R \times \mathrm{C}_{\text {out }} \times \mathrm{V}_{\text {OUT }}}{\Delta I_{\text {step }}}=\frac{\mathrm{ESR}_{\mathrm{E}} \times \mathrm{C}_{\mathrm{E}} \times \mathrm{V}_{\text {OUT }}}{\Delta \mathrm{I}_{\text {step }}} \tag{8}
\end{align*}
$$

where $\mathrm{ESR}_{\mathrm{E}}$ and $\mathrm{C}_{\mathrm{E}}$ represents ESR and capacitance of each capacitor if multiple capacitors are used in parallel.

The above equation shows that if the selected output inductor is smaller than the critical inductance, the voltage droop or overshoot is only dependent on the ESR of output capacitor. For low frequency capacitor such as electrolytic capacitor, the product of ESR and capacitance is high and $\mathrm{L} \leq \mathrm{L}_{\text {crit }}$ is true. In that case, the transient spec is dependent on the ESR of capacitor.

In most cases, the output capacitors are multiple capacitors in parallel. The number of capacitors can be calculated by the following

$$
\begin{equation*}
\mathrm{N}=\frac{\mathrm{ESR}_{\mathrm{E}} \times \Delta \mathrm{I}_{\text {sep }}}{\Delta \mathrm{V}_{\text {tran }}}+\frac{\mathrm{V}_{\text {OUT }}}{2 \times \mathrm{L} \times \mathrm{C}_{\mathrm{E}} \times \Delta \mathrm{V}_{\text {tran }}} \times \tau^{2} \tag{9}
\end{equation*}
$$

where

$$
\tau=\left\{\begin{array}{l}
0 \\
\text { if } \quad L_{\text {EFF }}
\end{array} \leq L_{\text {crit }} \quad\left[\begin{array}{l}
\frac{L_{\text {EFF }} \times \Delta \mathrm{I}_{\text {sep }}}{\mathrm{V}_{\text {OUT }}}-\mathrm{ESR}_{\mathrm{E}} \times \mathrm{C}_{\mathrm{E}} \quad \text { if } \quad \mathrm{L}_{\text {EFF }} \geq \mathrm{L}_{\text {crit }}
\end{array}\right.\right.
$$

For example, assume voltage droop during transient is 120 mV for 30 A load step.

If the OS-CON capacitors ( $1000 \mathrm{uF}, 7 \mathrm{~m} \Omega$ ) is used, the critical inductance is given as

$$
\begin{aligned}
& \mathrm{L}_{\text {citi }}=\frac{\mathrm{ESR}_{\mathrm{E}} \times \mathrm{C}_{\mathrm{E}} \times \mathrm{V}_{\text {OUT }}}{\Delta \mathrm{I}_{\text {sep }}}= \\
& \frac{7 \mathrm{~m} \Omega \times 1000 \mu \mathrm{~F} \times 1.2 \mathrm{~V}}{30 \mathrm{~A}}=0.28 \mu \mathrm{H}
\end{aligned}
$$

The effective inductor value is 0.34 uH which is bigger than critical inductance. In that case, the output voltage transient not only dependent on the ESR, but also capacitance.
number of capacitors is

$$
\begin{aligned}
& \tau=\frac{\mathrm{L}_{\text {EFF }} \times \Delta \mathrm{I}_{\text {step }}}{\mathrm{V}_{\text {OUT }}}-\mathrm{ESR}_{\mathrm{E}} \times \mathrm{C}_{\mathrm{E}} \\
& =\frac{0.34 \mu \mathrm{H} \times 30 \mathrm{~A}}{1.2 \mathrm{~V}}-7 \mathrm{~m} \Omega \times 1000 \mu \mathrm{~F}=1.5 \mathrm{us} \\
& \mathrm{~N}=\frac{\mathrm{ESR}_{\mathrm{E}} \times \Delta \mathrm{I}_{\text {step }}}{\Delta \mathrm{V}_{\text {tan }}}+\frac{\mathrm{V}_{\text {OUT }}}{2 \times \mathrm{L}_{\mathrm{EFF}} \times \mathrm{C}_{\mathrm{E}} \times \Delta \mathrm{V}_{\text {tran }}} \times \tau^{2} \\
& =\frac{7 \mathrm{~m} \Omega \times 30 \mathrm{~A}}{120 \mathrm{mV}}+ \\
& \frac{1.2 \mathrm{~V}}{2 \times 0.34 \mu \mathrm{H} \times 1000 \mu \mathrm{~F} \times 120 \mathrm{mV}} \times(1.5 \mathrm{us})^{2} \\
& =1.78
\end{aligned}
$$

The number of capacitors has to satisfied both ripple and transient requirement. Overall, we can choose $\mathrm{N}=2$.

It should be considered that the proposed equation is based on ideal case, in reality, the droop or overshoot is typically more than the calculation. The equation gives a good start. For more margin, more capacitors have to be chosen after the test. Typically, for high frequency capacitor such as high quality POSCAP especially ceramic capacitor, $20 \%$ to $100 \%$ (for ceramic) more capacitors have to be chosen since the ESR of capacitors is so low that the PCB parasitic can affect the results tremendously. More capacitors have to be selected to compensate these parasitic parameters.

## Control Loop Compensator Design

NX2423 can control and drive two channel synchronous bucks with $180^{\circ}$ phase shift between each other. One of two channels is called master, the other is called slave. They are connected together by sharing the same output capacitors. Voltage loop is designed to regulate output voltage. In order to achieve the current balance in these two synchronous buck converters, current loop compensation network is employed to to make sure the currents in slave is following the master.

## Voltage Loop Compensator Design

Due to the double pole generated by LC filter of the power stage, the power system has $180^{\circ}$ phase shift , and therefore, is unstable by itself. In order to achieve accurate output voltage and fast transient response,compensator is employed to provide highest possible bandwidth and enough phase margin. Ideally, the Bode plot of the closed loop system has crossover frequency between $1 / 10$ and $1 / 5$ of the switching frequency, phase margin greater than $50^{\circ}$ and the gain crossing 0 dB with $-20 \mathrm{~dB} /$ decade. Power stage output capacitors usually decide the compensator type. If electrolytic capacitors are chosen as output capacitors, type II compensator can be used to compensate the system, because the zero caused by output capacitor ESR is lower than crossover frequency. Otherwise type III compensator should be chosen.

## A. Type II compensator design

If the electrolytic capacitors are chosen as power stage output capacitors, usually the Type II compensator can be used to compensate the system.

Type II compensator can be realized by simple RC circuit without feedback as shown in figure 3. R3 and C1 introduce a zero to cancel the double pole effect. C2 introduces a pole to suppress the switching noise. The following equations show the compensator pole zero location and constant gain.
Gain $=\frac{R_{3}}{R_{2}}$
$\mathrm{F}_{\mathrm{z}}=\frac{1}{2 \times \pi \times \mathrm{R}_{3} \times \mathrm{C}_{1}}$

$$
\begin{equation*}
\mathrm{F}_{\mathrm{p}} \approx \frac{1}{2 \times \pi \times \mathrm{R}_{3} \times \mathrm{C}_{2}} \tag{12}
\end{equation*}
$$

Figure 3 - Type II compensator

Figure 4 - Bode plot of Type II compensator

For this type of compensator, $\mathrm{F}_{\mathrm{o}}$ has to satisfy $F_{\mathrm{LC}}<\mathrm{F}_{\mathrm{ESR}} \ll \mathrm{F}_{\mathrm{o}}$ and $\mathrm{F}_{\mathrm{o}}<=1 / 10 \sim 1 / 5 \mathrm{~F}_{\mathrm{s}}$.

Here a type II compensator is designed for the case which has six electrolytic capacitors(1800uF, 13m $\Omega$ ) and
two 1.5 uH inductors.
1.Calculate the location of $L C$ double pole $F_{L C}$ and ESR zero $F_{E S R}$.

$$
\begin{aligned}
\mathrm{F}_{\text {LC }} & =\frac{1}{2 \times \pi \times \sqrt{\mathrm{L}_{\text {EFF }} \times \mathrm{C}_{\text {OUT }}}} \\
& =\frac{1}{2 \times \pi \times \sqrt{0.75 \mathrm{uH} \times 10800 \mathrm{uF}}} \\
& =1.768 \mathrm{kHz}
\end{aligned}
$$

$$
\begin{aligned}
\mathrm{F}_{\text {ESR }} & =\frac{1}{2 \times \pi \times \mathrm{ESR} \times \mathrm{C}_{\text {out }}} \\
& =\frac{1}{2 \times \pi \times 13 \mathrm{~m} \Omega \times 1800 \mathrm{uF}} \\
& =6.801 \mathrm{kHz}
\end{aligned}
$$

2. Set $R_{2}$ equal to $10 \mathrm{k} \Omega$ and calculate $R_{1}$.

$$
R_{1}=\frac{R_{2} \times V_{\text {REF }}}{V_{\text {OUT }}-V_{\text {REF }}}=\frac{10 \mathrm{k} \Omega \times 0.6 \mathrm{~V}}{1.2 \mathrm{~V}-0.6 \mathrm{~V}}=10 \mathrm{k} \Omega
$$

3. Set crossover frequency $\mathrm{F}_{\mathrm{o}}=15 \mathrm{kHz}$.
4. Calculate $R_{3}$ value by the following equation.

$$
\begin{aligned}
R_{3} & =\frac{V_{\text {OSC }}}{V_{\text {in }}} \times \frac{2 \times \pi \times F_{O} \times L_{\text {EFF }}}{E S R} \times R_{2} \\
& =\frac{1 \mathrm{~V}}{12 \mathrm{~V}} \times \frac{2 \times \pi \times 15 \mathrm{kHz} \times 0.75 \mathrm{uH}}{2.16 \mathrm{~m} \Omega} \times 10 \mathrm{k} \Omega \\
& =27.3 \mathrm{k} \Omega
\end{aligned}
$$

Choose $\mathrm{R}_{3}=27.4 \mathrm{k} \Omega$.
5. Calculate $\mathrm{C}_{1}$ by setting compensator zero $\mathrm{F}_{\mathrm{z}}$ at $75 \%$ of the LC double pole.

$$
\begin{aligned}
\mathrm{C}_{1} & =\frac{1}{2 \times \pi \times \mathrm{R}_{3} \times \mathrm{F}_{\mathrm{z}}} \\
& =\frac{1}{2 \times \pi \times 27.4 \mathrm{k} \Omega \times 0.75 \times 1.768 \mathrm{kHz}} \\
& =4.4 \mathrm{nF}
\end{aligned}
$$

Choose $\mathrm{C}_{1}=4.7 \mathrm{nF}$.
6. Calculate $\mathrm{C}_{2}$ by setting compensator pole $\mathrm{F}_{\mathrm{p}}$ at half the swithing frequency.

$$
\begin{aligned}
\mathrm{C}_{2} & =\frac{1}{\pi \times \mathrm{R}_{3} \times \mathrm{F}_{\mathrm{s}}} \\
& =\frac{1}{\pi \times 27.4 \mathrm{k} \Omega \times 400 \mathrm{kHz}} \\
& =30 \mathrm{pF}
\end{aligned}
$$

## B. Type III compensator design

For low ESR output capacitors, typically such as Sanyo OSCON and POSCAP, the frequency of ESR zero caused by output capacitors is higher than the crossover frequency. In this case, it is necessary to compensate the system with type III compensator.

In design example, six electrolytic capacitors are used as output capacitors. The system is compensated with type III compensator. The following figures and equations show how to realize the this type III compensator with electrolytic capacitors.

$$
\begin{align*}
& \mathrm{F}_{\mathrm{Z} 1}=\frac{1}{2 \times \pi \times \mathrm{R}_{4} \times \mathrm{C}_{2}}  \tag{14}\\
& \mathrm{~F}_{\mathrm{Z} 2}=\frac{1}{2 \times \pi \times\left(\mathrm{R}_{2}+\mathrm{R}_{3}\right) \times \mathrm{C}_{3}}  \tag{15}\\
& \mathrm{~F}_{\mathrm{P} 1}=\frac{1}{2 \times \pi \times \mathrm{R}_{3} \times \mathrm{C}_{3}}  \tag{16}\\
& \mathrm{~F}_{\mathrm{P} 2}=\frac{1}{2 \times \pi \times \mathrm{R}_{4} \times \frac{\mathrm{C}_{1} \times \mathrm{C}_{2}}{\mathrm{C}_{1}+\mathrm{C}_{2}}} \tag{17}
\end{align*}
$$

where $\mathrm{F}_{\mathrm{z} 1}, \mathrm{~F}_{\mathrm{z} 2}, \mathrm{~F}_{\mathrm{P} 1}$ and $\mathrm{F}_{\mathrm{P} 2}$ are poles and zeros in the compensator.

Figure 5 - Type III compensator

Choose $\mathrm{C}_{2}=33 \mathrm{pF}$.

$$
R_{1}=\frac{R_{2} \times V_{\text {REF }}}{V_{\text {OUT }}-V_{\text {REF }}}=\frac{10 \mathrm{k} \Omega \times 0.6 \mathrm{~V}}{1.2 \mathrm{~V}-0.6 \mathrm{~V}}=10 \mathrm{k} \Omega
$$

Choose $\mathrm{R}_{1}=10 \mathrm{k} \Omega$.
3. Calculate $\mathrm{C}_{3}$ by setting $\mathrm{F}_{\mathrm{Z2}}=\mathrm{F}_{\mathrm{LC}}$ and $\mathrm{F}_{\mathrm{p} 1}=\mathrm{F}_{\mathrm{ESR}}$.

$$
\begin{aligned}
\mathrm{C}_{3} & =\frac{1}{2 \times \pi \times \mathrm{R}_{2}} \times\left(\frac{1}{\mathrm{~F}_{\mathrm{z} 2}}-\frac{1}{\mathrm{~F}_{\mathrm{p} 1}}\right) \\
& =\frac{1}{2 \times \pi \times 10 \mathrm{k} \Omega} \times\left(\frac{1}{6.1 \mathrm{kHz}}-\frac{1}{22.7 \mathrm{kHz}}\right) \\
& =1.9 \mathrm{nF}
\end{aligned}
$$

Choose $\mathrm{C}_{3}=1.8 \mathrm{nF}$.
5. Calculate $R_{3}$ by equation (13).

$$
\begin{aligned}
\mathrm{R}_{3} & =\frac{1}{2 \times \pi \times \mathrm{F}_{\mathrm{P} 1} \times \mathrm{C}_{3}} \\
& =\frac{1}{2 \times \pi \times 22.7 \mathrm{kHz} \times 1.8 \mathrm{nF}} \\
& =3.89 \mathrm{k} \Omega
\end{aligned}
$$

Choose $\mathrm{R}_{3}=3.92 \mathrm{k} \Omega$.
6. Calculate $R_{4}$ by choosing $F_{0}=40 \mathrm{kHz}$.

$$
\begin{aligned}
\mathrm{R}_{4} & =\frac{\mathrm{V}_{\text {OSC }}}{\mathrm{V}_{\text {in }}} \times \frac{2 \times \pi \times \mathrm{F}_{\mathrm{O}} \times \mathrm{L}_{\text {EFF }}}{\mathrm{ESR}} \times \frac{\mathrm{R}_{2} \times \mathrm{R}_{3}}{\mathrm{R}_{2}+\mathrm{R}_{3}} \\
& =\frac{1 \mathrm{~V}}{12 \mathrm{~V}} \times \frac{2 \times \pi \times 40 \mathrm{kHz} \times 0.34 \mathrm{uH}}{3.5 \mathrm{~m} \Omega} \times \frac{10 \mathrm{k} \Omega \times 3.92 \mathrm{k} \Omega}{10 \mathrm{k} \Omega+3.92 \mathrm{k} \Omega} \\
& =5.73 \mathrm{k} \Omega
\end{aligned}
$$

Choose $\mathrm{R}_{4}=5.62 \mathrm{k} \Omega$.
7. Calculate $C_{2}$ with zero $F_{z 1}$ at $75 \%$ of the $L C$ double pole by equation (11).

$$
\begin{aligned}
\mathrm{C}_{2} & =\frac{1}{2 \times \pi \times \mathrm{F}_{\mathrm{Z1}} \times \mathrm{R}_{4}} \\
& =\frac{1}{2 \times \pi \times 0.75 \times 6.1 \mathrm{kHz} \times 5.62 \mathrm{k} \Omega} \\
& =6.2 \mathrm{nF}
\end{aligned}
$$

Choose $\mathrm{C}_{2}=6.8 \mathrm{nF}$.
8. Calculate $C_{1}$ by equation (14) with pole $F_{p 2}$ at half the switching frequency.

$$
\begin{aligned}
\mathrm{C}_{1} & =\frac{1}{2 \times \pi \times \mathrm{R}_{4} \times \mathrm{F}_{\mathrm{P} 2}} \\
& =\frac{1}{2 \times \pi \times 5.62 \mathrm{k} \Omega \times 200 \mathrm{kHz}} \\
& =141 \mathrm{pF}
\end{aligned}
$$

Choose $\mathrm{C}_{1}=150 \mathrm{pF}$.

## Current Loop Compensator Design

Figure 7 - Current loop control diagram

Figure 8 - Function diagram of current loop

## Inductor Current Sensing

Figure 9 - Inductor current sensing using RC network.
The inductor current can be sensed through a RC network as shown above. The advantage of the RC network is the lossless comparing with a resistor in series with output inductor.

The selection of the resistor sensing network is chosen by the following equation:

$$
\begin{equation*}
\mathrm{R}_{\mathrm{s}} \times \mathrm{C}_{\mathrm{s}}=\frac{\mathrm{L}}{\mathrm{DCR}} \tag{18}
\end{equation*}
$$

If the above equation is satisfied, the voltage across the sensing capacitor Cs will be equal to the inductor current times DCR of inductor for all frequency domain.

$$
v_{s_{-}-\mathrm{L}}=D C R \times i_{L}
$$

If the sensing capacitor is chosen

$$
\mathrm{C}_{\mathrm{s}}=1 \mu \mathrm{~F}
$$

$\mathrm{C}_{s}$ must be X7R or COG ceramic capacitor.
The sensing resistor is calculated as

$$
\mathrm{R}_{\mathrm{s}}=\frac{\mathrm{L}}{\mathrm{DCR} \times \mathrm{C}_{\mathrm{s}}}
$$

For example, for 0.68 uH inductor with $1.4 \mathrm{~m} \Omega$ DCR, we have

$$
\mathrm{R}_{\mathrm{s}}=\frac{0.68 \mu \mathrm{H}}{1.4 \mathrm{~m} \Omega \times 1 \mu \mathrm{~F}}=486 \Omega
$$

In most of cases, the selection of sensing resistor based on the above equation will be sufficient. However, for some inductor such as toroid coiled inductor with micrometal, even the product of sensing resistor and capacitor is perfectly match with L/DCR, the voltage across the capacitor still has overshoot due to the nonlinearity of inductor. This will affect the droop accu-
racy during the transient if droop function is required. The illustration is shown in the following figure.

Figure 10 - Droop accuracy affected by the nonlinearity of inductor.

In this case, the sensing resistor has to be chosen

$$
\mathrm{R}_{\mathrm{s}} \geq \frac{\mathrm{L}}{\mathrm{DCR} \times \mathrm{C}_{\mathrm{s}}}
$$

to compensate the overshoot. This selection only affects the small signal mode of current loop. For DC accuracy, there is no effect since the DC voltage across the sensing capacitor will equal to the DCR times inductor current at DC load no matter what Rs is. In this example, $\mathrm{Rs}=620 \Omega$.
$R_{s}$ value is preferred to be less than $400 \Omega$ in NX2423's application, therefore we need to reiterate the calculation, choose $C_{s} 2.2 u F$ instead. $R_{s}$ value is finally chosen as $301 \Omega$.

Powe dissipation of Rs resistor is calculated as followed:

$$
\begin{aligned}
P_{\mathrm{D}}\left(\mathrm{R}_{\mathrm{S}}\right) & =\frac{\left(\mathrm{V}_{\text {IN }}-\mathrm{V}_{\text {OUT }}\right)^{2}}{\mathrm{R}_{\mathrm{S}}} \times \mathrm{D}+\frac{\mathrm{V}_{\text {OUT }}^{2}}{\mathrm{R}_{\mathrm{S}}} \times(1-\mathrm{D}) \\
& =\frac{(12 \mathrm{~V}-1.2 \mathrm{~V})^{2}}{301 \Omega} \times 0.1+\frac{(1.2 \mathrm{~V})^{2}}{301 \Omega} \times(1-0.1) \\
& =0.04 \mathrm{~W}
\end{aligned}
$$

The power rating of Rs should be over 0.04 W .

## Current Loop Compensation

Figure 11 - Bode plot of current loop
The diagram and bode plot for current loop of NX2423 is shown in above figure. The current signal through inductor sensing is amplified by current sensing differential amplifier. The amplified slave current signal is compared with the amplified inductor current from master channel (channel 1 for NX2423) through a transconductance amplifier, the difference between channel current will change the output of transconductance amplifier, which will compare with a internal ramp signal and changes the duty cycle of slave channel buck converter. If the inductor are perfectly matched and the PWM controller has no offset, the DC current in slave channel will equal to the DC current of master channel (channel 1) due to the gain of current loop.

From the bode plot, the power stage has one pole located at

$$
\mathrm{F}_{\mathrm{P} 1}=\frac{\mathrm{R}_{\mathrm{eq}}}{2 \times \pi \times \mathrm{L}}
$$

where $R_{e q}$ is the equivalent resistor and it is given by

$$
\mathrm{R}_{\text {eq }} \approx \mathrm{DCR}+\mathrm{R}_{\text {dson_con }} \times \frac{\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {IN }}}+\mathrm{R}_{\text {dson_syn }} \times\left(1-\frac{\mathrm{V}_{\text {out }}}{\mathrm{V}_{\text {IN }}}\right)
$$

$R_{\text {dson_con }}$ is the Rdson of control FET and $R_{\text {dson_syn }}$ is the Rdson of synchronous FET. For this example,

$$
\mathrm{R}_{\mathrm{eq}}=7.4 \mathrm{~m} \Omega
$$

The pole is located as

$$
\mathrm{F}_{\mathrm{P} 1}=\frac{\mathrm{R}_{\mathrm{eq}}}{2 \times \pi \times \mathrm{L}}=\frac{7.4 \mathrm{~m} \Omega}{2 \times \pi \times 0.68 \mu \mathrm{H}}=1.7 \mathrm{kHz}
$$

The current compensation transfer function is given as

$$
D(s)=\frac{g_{m}}{s \times\left(C_{1}+C_{2}\right)} \times \frac{1+s \times R_{c c} \times C_{1}}{1+s \times \frac{R_{c c} \times C_{1} \times C_{2}}{C_{1}+C_{2}}}
$$

It has one zero and one pole. The ideal is to choose resistor Rcc to achieve desired loop gain such as 50 kHz . Rcc can be calculated as

$$
\begin{equation*}
R_{\text {cc }}=\frac{2 \times \pi \times F_{0} \times L \times V_{\text {osc }}}{g_{m} \times V_{\text {IN }} \times K_{c} \times D C R} \tag{1}
\end{equation*}
$$

where

$$
\mathrm{K}_{\mathrm{c}} \approx \frac{60 \cdot \mathrm{k} \Omega}{2 \mathrm{k} \Omega+\mathrm{R}_{\mathrm{s}}}=22.9
$$

$60 \mathrm{k} \Omega$ and $2 \mathrm{k} \Omega$ is the internal resistance for the current sensing amplifier.

For fast response, we can set the current loop cross-over frequency one and half times of voltage loop cross-over frequency. Since the voltage loop cross-over frequency is typically selected as $1 / 10$ of switching frequency, we choose $\mathrm{F}_{\mathrm{o}}=50 \mathrm{kHz}$.

$$
\mathrm{R}_{\mathrm{cc}}=\frac{2 \times \pi \times 50 \mathrm{kHz} \times 0.68 \mu \mathrm{H} \times 1 \mathrm{~V}}{1.6 \mathrm{~mA} / \mathrm{V} \times 12 \mathrm{~V} \times 22.9 \times 1.4 \mathrm{~m} \Omega}=442 \Omega
$$

Select

$$
\mathrm{R}_{\mathrm{cc}}=430 \Omega
$$

The selection of capacitor $\mathrm{C}_{1}$ is such that the zero of compensation will cancel the pole of power stage, therefore,

$$
\mathrm{C}_{1}=\frac{\mathrm{L}}{\mathrm{R}_{\mathrm{eq}} \times \mathrm{R}_{\mathrm{cc}}}=\frac{0.68 \mu \mathrm{H}}{7.4 \mathrm{~m} \Omega \times 430 \Omega}=214 \mathrm{nF}
$$

Typically, the capacitor $\mathrm{C}_{1}$ is so big that the current loop may start slowly during the start up. Therefore, smaller capacitor can be selected. However, the selected capacitor can not reduce too much to cause phase droop.

Select $\mathrm{C}_{1}=220 \mathrm{nF}$.
The capacitor $\mathrm{C}_{2}$ is an option and it is used to filter out the switching noise. $\mathrm{C}_{2}$ can be calculated as

$$
\mathrm{C}_{2}=\frac{1}{\pi \times \mathrm{R}_{\mathrm{cc}} \times \mathrm{F}_{\mathrm{s}}}=\frac{1}{\pi \times 430 \Omega \times 400 \mathrm{kHz}}=1.85 \mathrm{nF}
$$

Select $\mathrm{C}_{2}=2.2 \mathrm{nF}$.

## Frequency Selection

The frequency can be set by external Rt resistor. The relationship between frequency per phase and RT pin around 400 kHz is shown as follows.

$$
\begin{equation*}
\mathrm{R}_{\mathrm{T}} \approx \frac{40000000}{\mathrm{~F}_{\mathrm{S}}} \tag{20}
\end{equation*}
$$

Fequanch(ktz) vsR(kdm)

Figure 12 - Frequency vs Rt chart

## Input Filter Selection

The selection criteria of input capacitor are voltage rating and the RMS current rating. For conservative consideration, the capacitor voltage rating should be 1.5 times higher than the maximum input voltage. The RMS current rating of the input capacitor for multi-phase converter can be estimated from the above Figure 13.

First, determine the duty cycle of the converter ( $\mathrm{V}_{\mathrm{o}} /$ $\mathrm{V}_{\text {IN }}$ ). The ratio of input RMS current over output current can be obtained. Then the total input RMS current can be calculated. From this figure, it is obvious that a multiphase converter can have a much smaller input RMS current, which results in a lower amount of input capacitors that are required.

For example, Vin=12V, Vout=1.2V. The duty cycle is $D=$ Vout/Vin=1.2/12=10\%. From the figure, for two phase, the normlized RMS current is
$0.2^{*}$ lout $=0.2^{*} 50 \mathrm{~A}=10 \mathrm{~A}$.
A combination of ceramic and electrolytic(SANYO WG or WF series) or OSCON type capacitors can achieve both ripple current capability together with having enough capacitance such that input voltage will not sag too much. In this application, one OSCON SVPC180M(180uF, 16V, 2.8A) and three 10uF X5R ceramic capacitors are selected.

A 1uH input inductor is recommended to slow down the input current transient. Suppose power stage efficiency is 0.8 , then input current can estimated by

$$
\mathrm{I}_{\text {INPUT }}=\frac{\mathrm{I}_{\text {OUT }} \times \mathrm{V}_{\text {OUT }}}{\eta \times \mathrm{V}_{\text {IN }}}=\frac{60 \mathrm{~A} \times 1.2 \mathrm{~V}}{0.8 \times 12 \mathrm{~V}}=7.5 \mathrm{~A}
$$

In this application, Coilcraft DO3316P_102HC with RMS rating 10A is chosen.

Figure 13 - Normalized input RMS current vs. duty cycle

## Over Current/Short Circuit Protection

The converter will go into hiccup mode if the output current reaches a programmed limit $I_{\text {OCP }}$ determined by the resistor value $\mathrm{R}_{\text {ocp }}$ at pin IOUT/IMAX.
$\mathrm{R}_{\mathrm{OCP}}=\frac{1.25 \mathrm{~V}}{0.04 \mathrm{~mA} / \mathrm{V}} \times \frac{2 \mathrm{k} \Omega+\mathrm{R}_{\mathrm{s}}}{60 \mathrm{k} \Omega} \times \frac{2}{\mathrm{DCR}} \times \frac{1}{\mathrm{l}_{\mathrm{OCP}}}$
Where $I_{\text {ocp }}$ is the desired over current protection level, $R_{s}$ is the current sensing matching resistor when using DCR sensing method.

## Over Voltage Protection

Over voltage protection is achieved by sensing the output voltage through resistor divider. The sensed voltage on FB pin is compared with $130 \%{ }^{*} V_{\text {REF }}$ to generate the OVP signal.

## Power MOSFETs Selection

The NX2423 requires two N -Channel power MOSFETs for each channels. The selection of MOSFETs is based on maximum drain source voltage, gate source voltage, maximum current rating, MOSFET on resistance and power dissipation. The main consideration is the power loss contribution of MOSFETs to the overall converter efficiency. In this design example, eight NTD60N02 are used. They have the following parameters: $V_{D S}=25 \mathrm{~V}, I_{D}=62 A, R_{\text {DSON }}=12 \mathrm{~m} \Omega, Q_{G A T E}=9 n C$.

There are three factors causing the MOSFET power loss:conduction loss, switching loss and gate driver loss.

Gate driver loss is the loss generated by discharging the gate capacitor and is dissipated in driver circuits. It is proportional to frequency and is defined as:

$$
\begin{equation*}
P_{\text {gate }}=\left(Q_{\text {HGATE }} \times V_{\text {HGS }}+Q_{\text {LGATE }} \times V_{\text {LGS }}\right) \times F_{S} \tag{22}
\end{equation*}
$$

where Qhgate is the high side MOSFETs gate charge, Qlgate is the low side MOSFETs gate charge, Vhas is the high side gate source voltage, and $\mathrm{V}_{\mathrm{LGS}}$ is the low side gate source voltage. This power dissipation should not exceed maximum power dissipation of the driver device.

Conduction loss is simply defined as:

$$
\begin{align*}
& \mathrm{P}_{\text {HCON }}=\mathrm{I}_{\text {OUT }}^{2} \times \mathrm{D} \times \mathrm{R}_{\text {DS(ON })} \times K \\
& \mathrm{P}_{\text {LCON }}=\mathrm{I}_{\text {OUT }}^{2} \times(1-\mathrm{D}) \times \mathrm{R}_{\text {DS(ON })} \times \mathrm{K} \\
& \mathrm{P}_{\text {TOTAL }}=\mathrm{P}_{\text {HCON }}+\mathrm{P}_{\text {LCON }}
\end{align*}
$$

Where the Rds(On) will increases as MOSFET junction temperature increases, K is $\mathrm{Ros}_{\mathrm{D}(\mathrm{ON})}$ temperature dependency and should be selected for the worst case. Conduction loss should not exceed package rating or overall system thermal budget.

Switching loss is mainly caused by crossover conduction at the switching transition. The total switching loss can be approximated.

$$
\begin{equation*}
P_{S W}=\frac{1}{2} \times V_{\text {IN }} \times I_{\text {OUT }} \times T_{\text {SW }} \times F_{S} \tag{24}
\end{equation*}
$$

$T_{S W}$ is the sum of $T_{R}$ and $T_{F}$ which can be found in mosfet datasheet, lout is output current, and Fs is switching frequency. Swithing loss Psw is frequency dependent.

## Soft Start and Enable Signal Operation

The NX2423's master channel will start operation after 5VCC and REFIN have reached their threshold voltages. Pulling down VCCDRV will cause 5VCC drop below to its threshold, then shuts down NX2423.

The slave channel will start operation only when EN2_B is less than 0.8V,5VCC and REFIN have reached their respective thresholds. For two phase opeartion, EN2_B is preferred to be tied to GND. For one phase opeartion, EN2_B is preferred to be tied to 5VCC. During the operation, it is not recommended to change EN2_B voltage.

Once the converter starts, there is a soft start sequence of 1024 steps between 0 and $\mathrm{V}_{\mathrm{REF}}$. The ramp rate is determined by the switching frequency.

$$
\begin{equation*}
\frac{d V_{\mathrm{O}}}{\mathrm{dt}}=\frac{\mathrm{V}_{\mathrm{O}}}{1024 \times \mathrm{T}_{\mathrm{s}}} \tag{25}
\end{equation*}
$$

## Layout Considerations

The layout is very important when designing high frequency switching converters. Layout will affect noise pickup and can cause a good design to perform with less than expected results.

There are two sets of components considered in the layout which are power components and small signal components. Power components usually consist of input capacitors, high-side MOSFET, low-side MOSFET, inductor and output capacitors. A noisy environment is generated by the power components due to the switching power. Small signal components are connected to sensitive pins or nodes. A multilayer layout which includes power plane, ground plane and signal plane is recommended.

Layout guidelines:

1. First put all the power components in the top layer connected by wide, copper filled areas. The input capacitor, inductor, output capacitor and the MOSFETs should be close to each other as possible. This helps to reduce the EMI radiated by the power loop due to the
high switching currents through them.
2. Low ESR capacitor which can handle input RMS ripple current and a high frequency decoupling ceramic cap which usually is 1 uF need to be practically touching the drain pin of the upper MOSFET, a plane connection is a must.
3. The output capacitors should be placed as close as to the load as possible and plane connection is required.
4. Drain of the low-side MOSFET and source of the high-side MOSFET need to be connected thru a plane ans as close as possible. A snubber nedds to be placed as close to this junction as possible.
5. Source of the lower MOSFET needs to be connected to the GND plane with multiple vias. One is not enough. This is very important. The same applies to the output capacitors and input capacitors.
6. Hdrv and Ldrv pins should be as close to MOSFET gate as possible. The gate traces should be wide and short. A place for gate drv resistors is needed to fine tune noise if needed.
7. Vcc capacitor, BST capacitor or any other bypassing capacitor needs to be placed first around the IC and as close as possible. The capacitor on comp to GND or comp back to FB needs to be place as close to the pin as well as resistor divider.
8. The output sense line which is sensing output back to the resistor divider should not go through high frequency signals.
9. All GNDs need to go directly thru via to GND plane.
10. The feedback part of the system should be kept away from the inductor and other noise sources, and be placed close to the IC.
11. In multilayer PCB, separate power ground and analog ground. These two grounds must be connected together on the PC board layout at a single point. The goal is to localize the high current path to a separate loop that does not interfere with the more sensitive analog control function.
12. Inductor current sense line should be connected directly to the inductor solder pad.
